A New Strategy against Hostile Takeovers: a Model of Defense in Participations

Abstract

This article examines the efficacy of a “defense in participations” policy consisting of competitors acquiring cross equity participations within the same industry to prevent hostile takeovers. This *defense in participations* strategy provides disincentive for raiders as partial ownerships increase market power of competitors and then reinforce the “outsider effect”. Also, we find conditions for a general result which states that takeovers are less profitable in an industry with participations rather than in an industry without any capital links. We provide information to regulators about the positive social impact of cross participations in the context of mergers, and expose an economic dilemma between a “laisser-faire” and an interventionist approach.

1 INTRODUCTION

A hostile takeover consists of buying shares of another corporation for the purpose of taking control of its management and of receiving its dividends. The raider (the acquiring firm) announces its desire to buy back targeted company’s shares at a premium. The level of the premium is set to encourage shareholders to sell their stake and also partially reflects potential synergies¹ of the merger. According to Manne (1965) and Jensen (1986), the primary synergies

¹ The takeover by Hewlett-Packard of Autonomy is an example of an excessive premium paid by the acquirer based on miscalculated synergies and goodwill value.

1
2
3 arise mostly from a change in the management because poorly controlled companies are easy
4 targets for raiders. Further, a substantial premium can prevent other competitors entering a bid
5 race for the acquisition of the firm. Achieving better results than competitors is the best defense
6 against raiders, but a hostile takeover does not always constitute a credible threat for
7 underperforming managers. Indeed, Grossman & Hart (1980) state that in the case of a takeover
8 both managers and shareholders will be harmed; however this idea is criticized by Deman (1994).
9 Numerous other strategies against hostile buyouts have been imagined and implemented such as:
10 Pac-Man², Shark Repellents, Crown Jewels, Poison Pills, or antitakeover provisions (ATPs). All
11 these strategies do not directly modify the capital structure of the target. However, in the context
12 of buyouts the question of capital appears to be crucial.
13
14

15 Most of the time, a takeover is preceded by a small acquisition of capital, a toehold which
16 proves beneficial to take control of the firm because it increases the amount necessary for
17 competitors to win the battle. Bulow et al. (1999) thus find that competitors have no incentive to
18 overbid the toehold acquirer, because of the winner's curse effect³. The literature related to
19 agency costs (Fama, 1980; Easterbrook, 1984), or to antitakeover amendments (DeAngelo &
20 Rice, 1983; Garell & Poulsen, 1987), and to toeholds (Choi, 1991; Betton et al., 2009) has
21 flourished. However fundamental questions on takeover incentives still remain. For example,
22 Inderst & Wey (2004) examine the profitability of takeovers in Bertrand and in Cournot
23 competing industries, where incentives increase along with substitutability and independency of
24 goods respectively.
25
26

27 To achieve diversification, the cross participations can be acquired in the capital of rivals
28 operating in the same or in different economic regions, into suppliers and clients firms, or
29 unrelated businesses. Partial ownerships can also be used to reinforce market power by
30 linking profit objectives of firms at the horizontal level (Perotti, 1992; Reitman, 1994), in a
31 vertical relationship (Greenlee & Raskovich, 2006), or in a mixed framework (Serbera, 2010).
32 The theoretical (see e.g. Malueg, 1992; O'Brien & Salop, 2000) and applied (see e.g. Reiffen,
33 1998) literature on partial ownerships is extensive but little exists on equity participations
34 strategies as a defense to hostile takeovers. An historic example of a defensive strategy appeared
35 during the first step of privatization of French State-owned companies (such as Saint-Gobain,
36 Paribas, Société Générale) starting in 1986: the "noyaux-durs" (or literally hard cores in English).
37
38

39 There are several examples of "defense in participations" policies equivalent across the
40 world:

41 -The "Keiretsu", which constitute a complex network of equity participations arranged by a bank
42 and linking corporations in Japan⁴ were widely studied in empirical literature (Flath, 1990;
43 Brown & Fung, 2009).
44

45 -The "Deutschland AG" (Franks & Mayer, 1998; Lantenois, 2011) which uses capital
46 arrangements to align the interests of the financial and industrial companies with those of the
47 employees whilst reducing the number of supervisory boards.
48

49 -The "golden shares"⁵ policy in the United Kingdom implemented during the Thatcher
50 privatization era (see Yergin & Stanislaw, 1998). The British government started acquiring a
51

52 ² The Pacman defense was named with reference to the famous video games' character; it consists of absorbing
53 competitors or in increasing capital to enhance firm's value.

54 ³ This is related to the theory of auctions in incomplete information. This effect states that the winner of the auction
55 overpays eventually ending up with a loss.

56 ⁴ Mitsubishi is an illustrative example of Keiretsu, its organization serves several purposes such as ease of financing,
57 independence of governance, diversification or market power.

58 ⁵ The term of golden shares is generically used to designate this type of participations arrangement.
59
60

1
2
3 small percentage of (preferred) shares of strategic companies such as Rolls-Royces, allowing it to
4 nominate board's members and apply a veto's power in certain circumstances.

5
6 All these "defenses in participations" consist of creating a core of shareholders through
7 over-the-counter shares acquisitions following advices from investment banks. More precisely,
8 freshly privatized companies were acquiring shares of capital in each other in order to constitute a
9 stable pool of stakeholders able to prevent any hostile takeover. The connection between BNP
10 Paribas and AXA acquiring around 5% of each other at the time⁶ in France, and Deutsche Bank
11 with an acquisition of 4.1% in Allianz in Germany, were famous examples of "golden shares".
12 Since the end of privatizations in western countries, these strategies are no longer imposed, but
13 existing shares still give governments a veto on major decisions such as takeovers. For example
14 in 2012, BAE's merger with EADS (now Airbus) was blocked by the UK government which
15 exercised its right to enforce the golden share rule. The particular case of the "noyaux-durs"
16 policy has been criticized afterwards by Goldstein (1996). He notes firstly, the make-up of the
17 core of shareholders was mostly based on financial considerations and missed the opportunity of
18 creating synergies following the participations arrangement. Secondly, the process of acquisition
19 of partial ownerships lacked transparency. As a consequence of its lack of transparency, the price
20 paid by the State for the shares did not include the control premium and was below the market
21 price paid by private investors.
22
23

24
25 More generally, despite criticisms of the opacity of the design and the implementation of
26 these governmental policies, the use of partial horizontal ownerships (PHO) as a defense against
27 hostile takeovers raises many questions. In the context of mergers' profitability and incentives,
28 when silent participations are possible we can cite Foros et al. (2011). They assert that the
29 accrued profitability resulting from a partial (but controlling) ownership arrangement is greater
30 than after a full merger. This greater profitability comes from increased barriers to entry after the
31 participations arrangement becomes publicly observable. In the case of a majority ownership, the
32 two firms are controlled by the same managers. However, in this article, we study the impact of a
33 *defense in participations* on takeover incentives in an industry where firms can acquire partial
34 non-controlling (also called silent⁷ or passive) and reciprocal shares (cross participations) in the
35 capital of competitors. In our model with silent ownerships, each management remains in place
36 and decides upon its own production despite internalizing rival's profit up to its participation
37 level. By using passive participations instead of controlling ones, we are thus able to differentiate
38 between the effect of participations and that of mergers. More precisely, this article highlights the
39 influence of cross participations on takeover incentives by determining their profitability in a
40 Cournot oligopoly model with n firms producing differentiated goods.
41
42

43
44 Our model finds a simple solution where PHO constitute an effective defense against
45 hostile takeovers by reducing incentives to raid protected firms inside the industry. As a more
46 general result, we show that when comparing two different industries, a hostile buyout is less
47 likely in an industry where companies use the *defense in participations* strategy rather than in an
48 industry without any capital links between the firms. We refine the result on the efficiency of the
49 *defense in participations* relatively to the number of competing firms, and we obtain the defense
50

51
52 ⁶ Ended in 2010

53 ⁷ Silent ownerships are a common practice between competing firms. In the case of listed firms all regulatory
54 ownerships thresholds are regularly reported to financial markets regulatory agencies. The type of shares determines
55 associated voting rights. As long as the ownership remains minority participation (below 50%) the only impact on
56 other firm managers' decisions is the co-integration of profits. As a consequence, this assumption rules out decisions
57 such as stopping activity or shutting down the partially acquired firm. In this paper we only consider participations
58 through class B shares (giving a claim on capital and no voting rights); this allows us to call them silent.
59
60

is more powerful in a less concentrated industry. In this case, a weaker market power leads to reduction of expected profits following a merger. The intuitive explanation of the efficiency of this defense strategy in PHO mainly arises from an increased “outsider effect⁸” of merger (see Salant et al., 1983) brought by the cross participations.

This study adds an innovative defense strategy against hostile takeovers to already existing ones, and opens the field for regulation in various ways. In a conservative approach this defense is effective against hostile buyouts over strategic sectors (weapons, nuclear, communications) from foreign competitors, but in a more liberal one it raises barriers against the self-regulation of the market (even if it leads to less competition).

2 Model and Set-Up

Table 1 presents detailed notations for the Cournot-Nash oligopoly model composed of n firms competing in quantities.

n	Number of firms in the industry
α	Cross partial ownership
γ	Substitutability parameter
p_i	Final price for good i
q_i	Output of good i
c	Marginal cost of production (constant)
π_i	Profit of Firm i
A	Demand Parameter (constant)

Tab. 1. Notation

Definition A *defense in participations* is a mutual agreement in which two firms acquire cross participations in the capital of each other.

(i) In the context of the defense policy, participations are set at an equal percentage: $\alpha_{12} = \alpha_{21} = \alpha$.

(ii) Equity holdings are silent minority stakes, giving the acquirer no right in the other firm management decisions.

Within the industry $I = \{1, \dots, n\}$, Firm 1 and Firm 2 are linked by symmetrical cross partial horizontal ownerships (PHO). As a consequence, we do not consider the stage of

⁸ In the context of an oligopoly, the “outsider effect” states that it is more beneficial to stay outside a merger than be part of it. As a reaction to the merger, outsiders increase their production more than the merged firm which internalize the profits of two firms, outsiders then end up more profitable.

participations choice in this model. Each firm behaves as an owner-managed⁹ entity.

Firms individually produce quantity of a substitutable good. The magnitude of substitutability depends on the substitutability parameter γ , $\gamma \in]0;1[$. We only consider substitutable goods in order¹⁰ to study the impact of participations and takeovers in a quantity competing oligopoly. For simplicity we assume that marginal costs of production, transformation and retail are constant. We suppose that the demand curve is linear: $p_i = A - q_i - \gamma \sum_{j \neq i} q_j$, $\forall i, \forall j$, $\in I$. Profit maximization considers operative profit (revenues minus costs), plus the share α in the capital of a rival (for linked firms only). The following figure illustrates the organization of the industry:

Fig. 1 The *defense in participations* in an oligopoly

We consider two distinct situations in this model. The first stage of the model discussed in Section 3 before any buyout. The second stage of the model discussed in Section 3.2.1-3.2.2 models the effects of the takeover. The effects of the takeover upon an unprotected firm (Section 3.2.1) and protected firms (Section 3.2.2) are discussed separately. By computing equilibrium profits we are able to compare pre and post-takeover profits and then derive firms' incentives to merge depending on their participations links α .

3 Solutions

3.1 Pre-Takeover

We begin the resolution of the model by the first stage, before any buyout. Before a hypothetical buyout, the industry is composed of n firms competing in quantities; each company behaves individually with the objective of maximizing its profit. Within the n firms only Firms 1-2 internalize profits of each other relative to the cross participation α . In the following, we

⁹ The company is both manager and principal shareholder; we thus avoid conflicts of interest.

¹⁰ When $\gamma = 0$, goods are independent and demand becomes inelastic, and as a consequence all firms produce the same output quantity up to their capacity constraints. Also, we set $\gamma \neq 1$ to differentiate consumer's demand vis-a-vis the firms' goods.

derive profits for Firms 1 and 2 linked by minority cross participations α , $\alpha \in]0;0.5[$:

$$\begin{aligned} \pi_1 = & (1-\alpha)(A-c-q_1-\gamma q_2-\gamma q_i-\gamma \sum_{j \in I \setminus \{1,2,i\}} q_j)q_1 \\ & +\alpha(A-c-\gamma q_1-q_2-\gamma q_i-\gamma \sum_{j \in I \setminus \{1,2,i\}} q_j)q_2 \end{aligned} \quad (1)$$

$$\begin{aligned} \pi_2 = & (1-\alpha)(A-c-\gamma q_1-q_2-\gamma q_i-\gamma \sum_{j \in I \setminus \{1,2,i\}} q_j)q_2 \\ & +\alpha(A-c-q_1-\gamma q_2-\gamma q_i-\gamma \sum_{j \in I \setminus \{1,2,i\}} q_j)q_1 \end{aligned} \quad (2)$$

Then, the profit of a firm without equity participations and representative of the majority of the industry can be calculated as

$$\pi_i = (A-c-\gamma q_1-\gamma q_2-q_i-\gamma \sum_{j \in I \setminus \{1,2,i\}} q_j)q_i \quad (3)$$

Solving simultaneously we obtain equilibrium quantities noted with a $*$. We thus observe that quantities q_1^* and q_2^* set by linked firms (with participation α) are inferior to quantities q_i^* set by other firms without PHO: $q_1^* = q_2^* < q_i^*$, the inequality holds for $\gamma \in]0;1[$. This expected result comes from partial internalization of cross profits. The more α increases, the more Firms 1 and 2 internalize profits of each other and cut their output. In turn, Firms 1-2 are incentivized to tacitly collude and this softens competition. But, in reaction to Firms 1-2 reduction in output, rival firms increase their own production and replace the lost quantities at the higher price. In the end, we obtain the traditional result of the “outsider effect” (see Salant et al., 1983): the one outside the participations benefit from the tacit collusion by capturing the additional revenue. Replacing equilibrium quantities found (1), (2) and (3) we thus obtain equilibrium profits. As the quantities from outsiders exceed insiders’ ones, the same is true for profits¹¹: $\pi_i^* > \pi_1^* = \pi_2^*$. In the following subsection, we study equilibrium profits of all firms in the industry after a takeover has happened.

3.2 Post-Takeover

In our study the raid is conducted by a firm outside¹² of the *defense in participations* in order to specifically test the solidity of this strategy of defense. We distinguish two cases for the buyout:
-Firstly, toward an unprotected (non-linked) firm
-Secondly, toward a protected firm (with participations).

3.2.1 Takeover of an Unprotected Firm

We then begin with Firm i taking over Firm j , both are unprotected. We note π_M the expression

¹¹ Please refer to the Appendix for the expression of equilibrium profits relevant to incentives calculations in Section 4.

¹² As our research places in the context of a defensive economic policy, the consequences of a protected firm raiding a competitor are left for further research on the subject.

of the new merged entity's profits. It maximizes joint profits of firms i and j relative to q_i and q_j :

$$\begin{aligned} \pi_M = & (A - c - \gamma q_1 - \gamma q_2 - q_i - \gamma q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_i \\ & + (A - c - \gamma q_1 - \gamma q_2 - \gamma q_i - q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_j \end{aligned} \quad (4)$$

Given the sum of these two concave¹³ profit functions is a concave function, we are able to determine the equilibrium output of the merged firm. Moreover, a symmetrical equilibrium can exist because reaction functions $q_i(q_{j,\cdot})$ and $q_j(q_{i,\cdot})$ are symmetrical, and by equalizing q_i and q_j we obtain a unique solution of post-merger quantity marked with an $_M$: q_M . The profit expression of the other firms does not move, but now Firms i and j have to be separated from other unprotected firms. We then introduce the notation q_l for quantities of unprotected outsiders. We first derive the profit expressions of the two protected firms:

$$\begin{aligned} \pi_1 = & (1 - \alpha)(A - c - q_1 - \gamma q_2 - \gamma q_i - \gamma q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_1 \\ & + \alpha(A - c - \gamma q_1 - q_2 - \gamma q_i - \gamma q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_2 \end{aligned} \quad (5)$$

$$\begin{aligned} \pi_2 = & (1 - \alpha)(A - c - \gamma q_1 - q_2 - \gamma q_i - \gamma q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_2 \\ & + \alpha(A - c - q_1 - \gamma q_2 - \gamma q_i - \gamma q_j - \gamma q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_1 \end{aligned} \quad (6)$$

These profit expressions being symmetrical ensures that equilibrium quantities will be symmetrical too. The profit expression for Firm k , unprotected and out of the merger, is derived as follows:

$$\pi_k = (A - c - \gamma q_1 - \gamma q_2 - \gamma q_i - \gamma q_j - q_k - \gamma \sum_{l \in I \setminus \{1, 2, i, j, k\}} q_l) q_k \quad (7)$$

Solving simultaneously for quantities, we obtain the expression of equilibrium quantities noted with a ** . By ranking these quantities we find: $q_M^{**} < q_1^{**} = q_2^{**} < q_k^{**}$, $\forall \gamma > 0$. Here also we obtain that the more the profits are integrated (partially with participations or totally for the buyout), the more the reduction of joint output is important. In the case of the merged firms, the output's decision is commonly set but each firm produces individually¹⁴. We expect that the profits will follow the same ranking: bigger profits for the unprotected firms and out of the buyout, then the defended firms and then merged firms. By replacing equilibrium quantities found in (5), (6), and (7) we obtain equilibrium profits. The ranking¹⁵ is expressed as follows:

$$\pi_k^{**} > \pi_1^{**} = \pi_2^{**} > \frac{\pi_M^{**}}{2} \text{ for any positive value of the parameters } n, c, \text{ or } \gamma. \text{ This comparison thus}$$

¹³ Please refer to the Appendix for the proof of concavity of the firms' individual profit functions.

¹⁴ The two firms (having symmetrical profit functions) choose the same individual output.

¹⁵ Please note that in this ranking we consider $\pi_M^{**}/2$ as the merged entity includes the sum of the two firms' profits with double q_M quantities.

confirms the role of the “outsider effect” on profitability. This result appears as a preview for the study of buyout incentives in Section 4. In the following, we study the second case of a takeover equilibrium with one of the two protected firms being the target.

3.2.2 Takeover of a Protected Firm

We consider here that Firm i launches a raid on Firm 1, the following expression marked with a $'_M$ is a sum of: Firm 1’s profit plus the portion α of profit held in Firm 2 plus the whole profit of the raider (Firm i):

$$\begin{aligned} \pi'_M = & (1-\alpha)(A-c-q_1-\gamma q_2-\gamma q_i-\gamma q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_1 \\ & +\alpha(A-c-\gamma q_1-q_2-\gamma q_i-\gamma q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_2 \\ & +(A-c-\gamma q_1-\gamma q_2-q_i-\gamma q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_i \end{aligned} \quad (8)$$

π_1 and π_i being concaves, then π'_M is concave. Furthermore, the expression of π'_M being asymmetrical, we obtain two non-symmetrical reaction functions as a result of maximization of a single profit. The profit expressions for the other firms (Firm 2 and Firm j) are as follows:

$$\begin{aligned} \pi_2 = & (1-\alpha)(A-c-\gamma q_1-q_2-\gamma q_i-\gamma q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_2 \\ & +\alpha(A-c-q_1-\gamma q_2-\gamma q_i-\gamma q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_1 \end{aligned} \quad (9)$$

$$\pi_j = (A-c-\gamma q_1-\gamma q_2-\gamma q_i-q_j-\gamma \sum_{k \in I \setminus \{1,2,i,j\}} q_k)q_j \quad (10)$$

We derive reaction functions for Firms 2 and j , and then by solving simultaneously the four reactions functions we obtain equilibrium output quantities noted with a *** . We then derive a ranking: $q_1^{***} < q_i^{***} < q_2^{***} < q_j^{***}$ which is a consequence (once again) of the outsider’s effect. More explicitly, profit internalizing firms tacitly collude and reduce their output relative to the magnitude of their holdings. Firm j ¹⁶ which is not internalizing any rival’s profit set the greater quantity of output at equilibrium for a uniform price and thus generates the greater individual profit. We also find a similar ranking for profits and quantities with $\pi_j^{***} > \pi_2^{***} > \frac{\pi'_M}{2}$. These differences arise from the magnitude of profit internalization and are a consequence of the “outsider effect”. So far, we have computed equilibrium profits before the takeover, then in the case of raids on a protected and on an unprotected firm. In the following section we study firms’ incentives for a takeover in a comparative static framework.

4 Incentives

¹⁶ Firm j is representative of the $n-3$ firms outside of participation arrangements and of the takeover.

In this section we consider two cases:

- 1- When the raid is on an unprotected firm (Section 4.1).
- 2- When the raid is on a protected firm linked by participations (Section 4.2).

We first define and compute the insider's and outsider's "impact" of a takeover, and then we define and compute the takeover incentives in each case using the two impacts previously calculated.

4.1 Incentives to Raid an Unprotected Firm

We use here comparative static to obtain the impact on a raider of triggering a hostile takeover of an unprotected firm. Insider's impact is defined as the comparison between individual profits before the acquisition and joint profits¹⁷ of the raider after acquisition. The impact of the merger on insider's profits is noted I_M and is computed by subtracting from the new merged firm (π_M^{**}) the sum of the two unprotected individual firms (π_i^* and π_j^*) profits before the buyout. Thus,

$$I_M = (\pi_M^{**} - \pi_i^* - \pi_j^*) = (\pi_M^{**} - 2\pi_i^*) \quad (11)$$

The sign of equation (11) is ambiguous and depends on the value of parameters of the model. After a study of the difference in equilibrium profits (the impact I_M), the most crucial factor is the value¹⁸ of the substitutability parameter γ . I_M is positive for low values of γ . The profitability of the raid (on an unprotected firm) has to be positive to study the effects of the *defense in participations*, we thus pose it as a condition for the rest of the study. We then investigate merger profitability for low values of γ . Further, an increase in market power with higher values of PHO α and lower number n of firms increases merger's profitability. Indeed, a buyout in a more concentrated industry¹⁹ will always be more beneficial for the raider due to a greater increase in market power. Finally, it is straightforward to derive that the cost parameter c decreases profitability of a merger for all positive values.

After the study of takeover impact on the insiders, we now study the outsider's impact on an unprotected outsider's firm in order to determine final incentives to merge (the comparison of the respective impacts). Outsider's impact I_{out} represents the outsider's profitability of staying outside a raid on an unprotected firm within the industry. It is defined as the comparison between individual profits of a non-raider firm before the acquisition and its individual profits after acquisition. It is computed in a similar manner to equation (11), by subtracting the pre-takeover value of an unprotected outsider profits ($\pi_k^* = \pi_i^*$) from the value of an unprotected outsider post-takeover profit (π_k^{**}):

$$I_{out} = (\pi_k^{**} - \pi_i^*) \quad (12)$$

¹⁷ The merged firm profit includes the sum of the two previous individual profits.

¹⁸ All parameter solutions are graphically presented in the proofs in the Appendix.

¹⁹ Reducing the number of firms from 4 to 3 leads to a bigger increase in concentration than a reduction from 100 to 99 (25% versus 1% respectively).

This expression has a positive sign for all (positive) values of the model parameters, meaning that outsider firms are always better off when there is a takeover in the industry. This phenomenon is due to the “outsider effect” which is reinforced when market power in the industry is stronger (i.e. for greater values of α and lower values of n).

Finally, we define incentives which trigger a takeover. These incentives are determined by subtracting the impact of staying out of a takeover from the impact of launching a raid: $I_M - I_{out}$. We obtain that $I_M - I_{out} < 0$ for all (positive) values of the model parameters. Further, this negative incentive is reinforced when market power in the industry is stronger (i.e. for greater values of α and lower values of n). We conclude that in an industry where cross participations are possible it is always more profitable for a company to stay outside of an acquisition on an unprotected firm rather than to trigger a takeover. This result is consistent with the results of the “outsider effect” of mergers.

4.2 Incentives to raid a Protected Firm

Using the same process as in Section 4.1, we note I'_M the impact on insiders' profits of acquiring a firm protected by a *defense in participations*. In this case Firm i raids Firm 1 which is protected by a *defense in participations* with Firm 2. This insider's impact is derived by subtracting the sum of individual profits of the two insiders firms (π_1^* and π_i^*) before the takeover from the profit expression of the new merged (π_M^{***}) firm:

$$I'_M = (\pi_M^{***} - \pi_1^* - \pi_i^*) \quad (13)$$

The sign of equation (13) is ambiguous, and as in the previous case it depends on the values of the parameter γ in particular. For low values of γ this expression is negative (whereas I_M is positive). Further, this negative impact is reinforced when market power in the industry is stronger (i.e. for greater values of α and lower values of n). The cost parameter c has a negative influence on profitability.

The impact on outsiders' profits in this case is noted I'_{out} . It is computed by subtracting pre-takeover profit of an unprotected firm ($\pi_j^* = \pi_i^*$) from the individual outsider profit after the buyout (π_j^{***}):

$$I'_{out} = (\pi_j^{***} - \pi_i^*) \quad (14)$$

In this case of a raid on a protected firm, outsiders' profit impact is negative for low values of γ , but greater than I'_M . Further, this negative impact is reinforced when market power in the industry is stronger (i.e. for greater values of α and lower values of n). The cost parameter c has a negative influence on profitability.

In this case of a raid on a protected firm, we use the same method to obtain the choice's incentives to raid a rival firm or not. They are derived by subtracting outsider's impact from insider's impact: $I'_M - I'_{out}$. We find that $I'_M - I'_{out} < 0$ for low values of parameter γ . Further,

1
2
3 this negative incentive is reinforced when market power in the industry is stronger. The cost
4 parameter c has a negative influence on profitability. Here also, the increase in profits for
5 outsiders is more important. This leads us to conclude that in an industry where cross
6 participations are possible it is always more profitable for a company to stay outside of an
7 acquisition of a protected firm rather than to trigger it. This result is consistent with the “outsider
8 effect” result of mergers.
9

10 In Section 4, we determined a firm’s incentives to raid a protected or an unprotected rival
11 in accordance with “the outsider effect” result of mergers. In Section 5.1, we test the efficacy of
12 the defense in participations by comparing the values of the merger impacts I_M and I'_M .
13 Further, we expand the study area in Section 5.2 by comparing the impact of a takeover in a
14 protected industry (with linked firms) with the impact of a takeover in an oligopoly industry
15 where there are no PHO (a benchmark).
16
17

18 19 20 **5 Results and Propositions**

21
22 In this section, we demonstrate the efficiency of the *defense in participations* by comparing
23 takeover incentives on a protected firm versus those on an unprotected firm in a protected
24 industry (with firms acquiring participations). Further we expand the study to compare takeovers
25 in a protected versus an unprotected industry (the benchmark).
26
27

28 29 **5.1 Within an Industry with Participations**

30
31 We compare the insider’s impact on an unprotected firm I_M (positive for low values of γ) with
32 the insider’s impact on a protected firm I'_M . The whole expression $I_M - I'_M$ is positive, and
33 these incentives (within the industry) are reinforced by market power. This leads to a simple
34 conclusion: takeover incentives on an unprotected firm are higher than those on a protected firm
35 in a protected industry. The following proposition states this result:
36
37

38
39 *Proposition 1: The holding of cross participations in the capital of a competitor is an efficient*
40 *defense against a hostile takeover.*
41

42 This proposition is explained by the value of the takeover impact. Since it is lower on an
43 protected firm due to an increased “outsider effect”, a rational raider will prefer to raid an
44 unprotected target.
45
46

47 48 **5.2 Within an Industry without Participations**

49
50 As a first step, we use an insider’s impact in a common Cournot oligopoly benchmark to expand
51 our study and result in a wider framework. The difference lies in the absence of participations in
52 this case. This insider impact follows the same computation method used previously, i.e.
53 comparing the sum of profits pre and post takeover. We note I''_M the insider’s impact in a
54 common (no participations) industry competing in quantities: the benchmark. The sign of this
55 expression is ambiguous, like in the participations’ framework, and strongly depends on the value
56 of the substitutability parameter γ . Here also, the takeover impact can still be positive for low
57
58
59
60

values of γ , and an increase in market power with a smaller number of firms (no participations α in this case) makes the takeover more profitable.

5.3 Comparison among Industries

As a second step, we now compare the insider's impact I_M on an unprotected firm²⁰ (in the case with participations) to insider's impact I_M'' in the benchmark. The sign of the difference $I_M - I_M''$ is ambiguous, it is negative for low values of γ when market power is strong enough, and especially when the number of firms is big enough. This comparison shows that takeover incentives (among industries) are greater when there is no *defense in participations*. We then can deduce that $I_M'' > I_M (> I_M')$. This result highlights that a takeover is less profitable in an industry with participations as the incentives to merge are lower. We state this result in the following proposition:

Proposition 2: A takeover is less profitable in an industry where two of the firms are linked with a defense in participations than in one where no firms have a participations arrangement.

This proposition is explained by the value of the (unprotected) takeover impact in an industry where two of the firms are defended with participations. Since it is lower due to an increased "outsider effect", a rational raider will prefer to raid a target in an industry without a *defense in participations*.

5.4 Regulation

In contrast to literature results on the anticompetitive role of horizontal participations (Reitman, 1994; Gilo et al., 2006) alone or as a toehold before a full takeover (Jovanovic & Wey, 2014), our analysis exposes the social benefits of PHO in our model. Indeed, the fact that participations constitute hurdles to hostile takeovers leads in the end to a less concentrated industry, even if in the beginning participations have lessened competition. These results have an implication in terms of regulation as they highlight the competitive role of cross horizontal participations.

The *defense in participations* in Europe with the "golden shares", "Deutschland AG" or "noyaux-durs" defers to the regulation of the European Commission and to the ruling the European Court of Justice (ECJ) in the case of a dispute. Special rights of the Union's members on private undertakings are discussed and examined to determine whether or not this falls within the ambit of the free movement of capital and payments. Lustig & Weil (2002) relate three ECJ rulings on participations and their link with corporate governance. In the case of Belgium, the ECJ granted the decision of giving notice to the responsible ministry of any changes in participations for the "Société Nationale de Transport par Canalisation" as well as the "Société de Distribution du Gaz SA" relating to a change in network facilities. In the case of France, the ECJ rejected the use of "golden shares" to secure approval of the Ministry of Economic Affairs when ceilings²¹ in participations were crossed for the "Société Nationale Elf-Aquitaine". Finally in the case of Portugal, the ECJ denied the justification of Portugal to use its participations to block

²⁰ Because we already shown that takeover incentives are greater on an unprotected firm than on a protected one.

²¹ 10%, 20%, or 30%.

1
2
3 foreign share acquisitions in privatised companies. In these three cases the European Commission
4 attacked the countries' decision to protect privatised companies using a *defense in participations*
5 on the basis of an infringement of the "laisser-faire" of the market (free movement of capital and
6 payments).
7

8 Our paper explores mathematically the competition approach on this topic, and our
9 theoretical results on the potential competitive role of PHO send a contrarian signal to the
10 regulation agencies and the courts. We argue that the regulators and governments could take into
11 account the findings introduced by this theoretical research to expand their comprehension of the
12 *defense in participations*. Though the *defense in participations* could be counter to the free
13 movement of capital on markets, it should be allowed under specific countries' strategic
14 circumstances (e.g. BAE-EADS merger) and also to counter the increase of concentration and
15 market power in a particular industry.
16
17

18 19 **6 Conclusion**

20
21 In this article, we study takeover incentives in a Cournot oligopoly model with two firms linked
22 by cross participations following an anti-takeover defense strategy. We show that within an
23 industry, PHO reduce incentives of competing firms to raid a protected firm by decreasing
24 takeover profitability. We thus demonstrate that the *defense in participations* is meaningful and
25 efficient to block hostile takeovers, and also has a competitive aspect. This competitive aspect is
26 proven by the comparison of takeover incentives between two industries, one with the *defense in*
27 *participations* and a benchmark without participations. As the full integration of a rival's profits
28 (buyout) is more harmful in terms of competition than partial ownerships, we suppose that
29 authorizing PHO could thus have social benefits.
30
31

32 Theoretical literature (see e.g. Malueg, 1992; O'brien & Salop, 2000) and applied work
33 (see e.g. Perotti, 1992; Reiffen, 1998) investigate participations but do not link them with
34 takeover incentives. Further, numerous articles highlight the role and functioning of different
35 forms of golden shares across several countries: (Flath, 1990; Brown & Fung, 2009) on Keiretsu,
36 Franks & Mayer (1998) and Lantenois (2011) on Deutschland AG, Yergin & Stanislaw (1998) on
37 UK golden shares, and Goldstein (1996) for French "noyaux-durs". In addition, Foros et al.
38 (2011) derive the profitability of a partial (but controlling) ownership. The role of our article is to
39 expose a theoretical study of the efficacy of the golden shares as a defense in participations in the
40 context of mergers.
41
42

43 To complement this article, a reverse study of the consequences of cross participations on
44 protected firms' incentives to raid competitors could be addressed in further research; this
45 protection could be used in this case to "attack" competitors. This should prove decisive in the
46 analysis of the influence of PHO on market concentration and on economic welfare. We believe
47 that this paper sheds new light on the current analysis of competition in the case of a defense in
48 participations. It also raises questions in the case of an "attack" and thus gives room for
49 additional investigations. Therefore this study of equity strategies, against or supporting a buyout,
50 could make policy makers change the current regulatory monitoring process and could intensify
51 applied research on the subject.
52

Appendix

Concavity of profits relative to quantities

To prove the concavity of profit functions we examine the second order condition and derive the sign of this expression.

We begin by the second order derivative of Firm i 's profit:

$$\frac{\partial^2 \pi_i}{\partial q_i^2} = -2 < 0$$

The second order derivative being negative, the profit function π_i is strictly concave relative to quantities.

We now study profit functions of defended firms 1 and 2 linked by cross participations α , their profit expressions are symmetrical:

$$\frac{\partial^2 \pi_1}{\partial q_1^2} = \frac{\partial^2 \pi_2}{\partial q_2^2} = -2 + 2\alpha < 0$$

The second order derivative is positive for partial ownership value of $\alpha < 1$.

Expression of equilibrium profits

Pre-takeover profits:

$$\pi_1^* = \pi_2^* = -\frac{(\gamma - 2)^2 (\alpha \gamma + 1 - \alpha) (A - c)^2 (-1 + \alpha)}{(-4\alpha\gamma^2 - 4\alpha + \gamma^2 + 4 - 4\gamma + 6\alpha\gamma + 2\gamma n - \gamma^2 n + 2\alpha\gamma^2 n - 2\alpha\gamma n)^2}$$

$$\pi_i^* = \frac{(-2\alpha + 2 + 2\alpha\gamma - \gamma)^2 (A - c)^2}{(-4\alpha\gamma^2 - 4\alpha + \gamma^2 + 4 - 4\gamma + 6\alpha\gamma + 2\gamma n - \gamma^2 n + 2\alpha\gamma^2 n - 2\alpha\gamma n)^2}$$

Profits after a takeover of an unprotected firm:

$$\pi_M^{**} = \frac{(1 + \gamma)(\gamma - 2)^2 (-\gamma + 2 + 2\alpha\gamma - 2\alpha)^2 (A - c)^2}{2(-2\alpha\gamma^2 + 6\alpha\gamma + \gamma^3 - \gamma^2 - 4\alpha - 2\alpha\gamma^3 - 4\gamma + 4 + 2\alpha\gamma^2 n - \gamma^2 n - 2\alpha\gamma n + 2\gamma n)^2}$$

$$\pi_k^{**} = \frac{(-\gamma + 2 + 2\alpha\gamma - 2\alpha)^2 (A - c)^2}{(-2\alpha\gamma^2 + 6\alpha\gamma + \gamma^3 - \gamma^2 - 4\alpha - 2\alpha\gamma^3 - 4\gamma + 4 + 2\alpha\gamma^2 n - \gamma^2 n - 2\alpha\gamma n + 2\gamma n)^2}$$

Profits after a takeover of a protected firm:

$$\pi_M^{****} = \frac{9(\alpha - 2)(193\alpha^3 - 475\alpha^2 + 392\alpha - 108)(-c + A)^2}{2(-24\alpha n + 39\alpha^2 + 11\alpha^2 n + 30 - 69\alpha + 12n)^2}$$

$$\pi_j^{***} = \frac{4(-24\alpha + 11\alpha^2 + 12)^2(-c + A)^2}{(-24\alpha n + 39\alpha^2 + 11\alpha^2 n + 30 - 69\alpha + 12n)^2}$$

Sign study of impacts

In the following, we represent graphically the value of I_M as a function of γ , n , and α .

Fig 2. I_M as a function of model parameters.

We highlight here the positive value of I_M for low values of γ . Further, we expose the positive relationship between the unprotected merger's impact I_M and the market power.

In the following, we represent graphically the value of I_M' as a function of γ , n , and α .

Fig 3. I_M' as a function of model parameters.

We highlight here the negative value of I_M' for low values of γ . Further, we expose the negative relationship between the protected merger's impact I_M' and the market power.

In the following, we represent graphically the value of I_M'' as a function of γ , and n .

Fig 4. I_M'' as a function of model parameters.

We highlight here the positive value of I_M'' for low values of γ . Further, we expose the positive relationship between the benchmark merger's impact I_M'' and the market power (a small number of firms, no participations in the benchmark).

The study of these takeover impacts describes the links between the profitability of a merger and the market power, depending on the type of takeover. In addition, we expose positive values of I_M and I_M'' for low values of γ , and this thus justifies the proposed condition.

Sign study of incentives

In the following, we represent graphically the value of the incentives to raid a protected firm: $I_M - I_{out}$ as a function of γ , n , and α .

Fig 5. $I_M - I_{out}$ as a function of model parameters.

We highlight here the negative value of the incentives to raid an unprotected firm: $I_M - I_{out} < 0$ for all values of γ . Further, this negative incentive is reinforced when market power in the industry is stronger.

In the following, we represent graphically the value of the incentives to raid a protected firm: $I'_M - I'_{out}$ as a function of γ , n , and α .

Fig 6. $I'_M - I'_{out}$ as a function of model parameters.

We highlight here the negative value of the incentives to raid a protected firm:

$I'_M - I'_{out} < 0$ for low to average values of γ . Further, this negative incentive is reinforced when market power in the industry is stronger.

The study of these two differences allows us to expose that in an industry where cross participations are possible it is always more profitable for a company to stay outside of an acquisition rather than to trigger it. This result is consistent with the “outsider effect”.

In the following, we represent graphically the value of the incentives within the same industry: $I_M - I'_M$, as a function of γ , n , and α .

Fig 7. $I_M - I'_M$ as a function of model parameters.

We highlight here the positive value of the incentives to raid an unprotected firm versus a protected one in a protected industry. $I_M - I'_M > 0$ for low to average values of γ . Further, this positive incentive is reinforced when market power in the industry is stronger.

In the following, we represent graphically the value of the incentives among different industries: $I_M - I''_M$ as a function of γ , n , and α .

Fig 8. $I_M - I_M''$ as a function of model parameters.

We highlight here the negative value of incentives to raid an unprotected firm versus the benchmark across different industries. $I_M - I_M'' < 0$ for low to high values of γ , and a sufficiently high value of n . Adding precisions for low values of γ (but not extremely close²² to 0) this result holds with the condition that I_M and I_M'' are positive. Further, the amount α of the participations decreases the profitability of a takeover in a protected industry in comparison to an unprotected one.

The study of these two differences yields $I_M'' > I_M (> I_M')$ which allows us to compare the incentives across the different industries in subsection 5.3 and to derive Proposition 2.
