Key indicators: powder synchrotron study; $T = 298$ K; mean $\sigma(\text{As}-\text{O}) = 0.040$ Å; R factor = 0.059; wR factor = 0.082; data-to-parameter ratio = 22.1.

The apatite-type compound Ba₅(AsO₄)₃Cl, pentabarium tris[arsenate(V)] chloride, has been synthesized by ion exchange at high temperature from a synthetic sample of mimetite (Pb₅(AsO₄)₃Cl) with BaCO₃ as a by-product. The results of the Rietveld refinement, based on high resolution synchrotron X-ray powder diffraction data, show that the title compound crystallizes in the same structure as other halogenoapatites with general formula A₅(YO₄)₃X (A = divalent cation, Y = pentavalent cation, X = Cl, Br) in space group $P6_3/m$. The structure consists of isolated tetrahedral AsO₄³⁻ anions (m symmetry), separated by two crystallographically independent Ba²⁺ cations that are located on mirror planes and threefold rotation axes, respectively. The Cl⁻ anions are at the $2b$ sites ($\bar{3}$ symmetry) and are located in the channels of the structure.

Rietveld refinement of Ba₅(AsO₄)₃Cl from high-resolution synchrotron data

A. M. T. Bell, C. M. B. Henderson, R. F. Wendlandt and W. J. Harrison

Comment

Apatites are minerals and synthetic compounds with general formula $A_5(YO_4)_3X$, containing tetrahedrally coordinated YO_4^{3-} anions (Y = pentavalent cation) and a monovalent anion X such as F^- , Cl^- or OH^- . The divalent cations frequently belong to the alkaline earth group, but other cations like Pb^{2+} are also known. For a review of the structures and crystal-chemistry of these materials, see Mercier *et al.* (2005) and White & Dong (2003). Apatites containing arsenic (As-apatites) are of interest as hosts for storage of arsenic removed from contaminated water (Harrison *et al.*, 2002). Powder diffraction data for the Ba containing As-apatites Ba₅(AsO₄)₃Cl (Kreidler & Hummel, 1970) and for (Ba_{2.25}Ca_{1.65}Pb_{1.16}Fe_{0.06}Mg_{0.06})[(AsO₄)_{2.56}(PO₄)_{0.3}]Cl_{1.09} (mineral name morelandite; Dunn & Rouse, 1978) were indexed in space group $P6_3/m$. Related crystal structures have also been reported for Ba₅(AsO₄)₂SO₄S (Schiff-Francois *et al.*, 1979) and (Sr_{1.66}Ba_{0.34})(Ba_{2.61}Sr_{0.39})(AsO₄)₃Cl (Dordevic *et al.*, 2008). The crystal structure of Ba₅(AsO₄)₃Cl in space group $P6_3/m$ is reported in the present communication.

Table 1 shows refined interatomic distances and angles for the Ba₅(AsO₄)₃Cl structure. The averaged Ba1—O and Ba2—O distances of respectively 2.87 Å and 2.84 Å are similar to those in other Ba and Cl containing apatites. In comparison, the average Ba1—O and Ba2—O distances are 2.84 Å and 2.78 Å for Ba₅(VO₄)₃Cl (Roh & Hong, 2005), 2.83 Å and 2.79 Å for Ba₅(PO₄)₃Cl (Hata *et al.*, 1979) and 2.83 Å and 2.76 Å for Ba₅(MnO₄)₃Cl (Reinen *et al.*, 1986). The As—O distances are characteristic for tetrahedral AsO₄ units. The O—As—O angles deviate significantly from the ideal tetrahedral angle of 109.5°, indicating a strong distortion.

The refined lattice parameters for Ba₅(AsO₄)₃Cl are similar to the previously published parameters of $a = 10.54$ Å, $c = 7.73$ Å given by Kreidler & Hummel (1970). A study of 108 existing and predicted apatites with different compositions made use of elemental radii to calculate their lattice parameters (Wu *et al.*, 2003). Only 52 of these compositions had known lattice parameters. The predicted lattice parameters for Ba₅(AsO₄)₃Cl were $a = 10.3979$ Å, $c = 7.6105$ Å. These predicted parameters are respectively 1.51% and 1.66% smaller than the measured lattice parameters, and only 2 of the 52 apatite compositions had bigger differences between observed and calculated lattice parameters.

Fig. 1 shows the Rietveld difference plot for the present refinement. The crystal structure of Ba₅(AsO₄)₃Cl, showing the isolated tetrahedral AsO₄³⁻ anions separated by Ba²⁺ cations and Cl⁻ anions, is displayed in Fig. 2.

Experimental

This work was part of an attempt to synthesize analogues of Pb₅(AsO₄)₃Cl (mimetite) with Pb²⁺ substituted by alkaline earth cations. All starting materials were well crystallized solids. Pb₅(AsO₄)₃Cl was precipitated by titration of 0.1M Na₂HAsO₄ into a well stirred, saturated PbCl₂ solution at room temperature (procedure modified from methods of Baker (1966) and

Essington (1988)). The molar ratio of Pb:As was slightly greater than 5:3, allowing for excess PbCl_2 during the precipitation. A very fine-grained pure solid formed immediately, which was then separated, washed, and dried. Typically, five de-ionized water washes were needed to reduced the conductivity of the wash water to $< 50 \mu\text{S}\cdot\text{cm}^{-1}$. $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ was successfully synthesized by ion exchange of $\text{Pb}_5(\text{AsO}_4)_3\text{Cl}$ with molten BaCl_2 at 1258 K (modified from the method given by Kreidler & Hummel (1970)). Two fusions were required to completely eliminate formation of Pb containing solid solutions and to yield the Pb free title compound. Excess metal in the form of BaCl_2 was removed from the solids by repeated washing with de-ionized water followed by centrifugation and filtration to separate the solid from the solution.

Refinement

The powdered sample was loaded into a 0.7 mm diameter borosilicate capillary, prior to high-resolution synchrotron X-ray powder diffraction data collection using station 9.1 of the Daresbury Synchrotron Radiation Source. The beam on the sample was 13 mm wide and 1.2 mm high. 9 powder datasets were collected, all were with a step with of $0.01^\circ/2\theta$ and a counting time of 2 s per point. Three of these datasets were collected between $5\text{--}70^\circ/2\theta$, two between $30\text{--}70^\circ/2\theta$, two between $40\text{--}70^\circ/2\theta$, one between $31.73\text{--}70^\circ/2\theta$ and one between $2\text{--}13.2^\circ/2\theta$. All of these data were summed and normalized to account for decay of the synchrotron beam with time. The main Bragg reflections of the powder diffraction pattern could be indexed in space group $P6_3/m$ with similar lattice parameters to those of the published powder diffraction data (Kreidler & Hummel, 1970). Some broad and weak Bragg reflections were matched by the pattern of BaCO_3 in space group $Pmcn$. The synchrotron X-ray wavelength was calibrated as 0.998043\AA with an external *NIST 640c* silicon standard reference material.

Initial lattice parameters for the two phases were refined using *CELREF* (Laugier & Bochu, 2003). The $P6_3/m$ crystal structure of $\text{Ba}_5(\text{PO}_4)_3(\text{OH})$ (Chengjun *et al.*, 2005) was used as a starting model for the Rietveld (Rietveld, 1969) refinement of the structure of $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$. The crystal structure of witherite (de Villiers *et al.*, 1971) was used as a starting model for refinement of the structure of BaCO_3 . Isotropic atomic displacement parameters were used for both phases. For the $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ phase the As—O distances in the AsO_4 tetrahedral units were constrained to those for mimetite (Dai *et al.*, 1991). For the BaCO_3 phase the C—O distances of the trigonal carbonate anion were constrained to those in witherite, and the U_{iso} factors for all atoms in the carbonate anion were constrained to be the same. As the $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ phase was prepared by ion-exchange of $\text{Pb}_5(\text{AsO}_4)_3\text{Cl}$, Rietveld refinements were done with the metal sites partially occupied by both Pb and Ba. However, this resulted in the refined Pb occupancies falling to zero. Therefore the occupancies of the metal sites were fixed as fully occupied by Ba and no Pb was included for the final refinement of the $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ phase. Proportions of the two phases were refined as 64.7 (9) wt.% $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ and 35.3 (9) wt.% BaCO_3 .

Figures

Fig. 1. Rietveld difference plot for the multi-phase refinement of $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ and BaCO_3 . The black dots, and grey and black lines show respectively the observed, calculated and difference plots. Calculated Bragg reflection positions are indicated by triangles for the $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$ phase and by crosses for the BaCO_3 phase.

Fig. 2. The crystal structure of $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$. Pink tetrahedra show AsO_4 units with As^{5+} cations as yellow spheres and O^{2-} anions as red spheres. Large blue spheres represent Ba^{2+} cations and small green spheres Cl^- anions.
