**Abstract.** Although tools exist to aid practitioners in the construction of directed graphs typified by Conceptual Graphs (CGs), it is still quite possible for them to draw the wrong model, mistakenly or otherwise. In larger or more complex CGs it is furthermore often difficult—without close inspection—to see clearly the key features of the model. This paper thereby presents a formal method, based on the exploitation of CGs as directed graphs and the application of Formal Concept Analysis (FCA). FCA elucidates key features of CGs such as pathways and dependencies, inputs and outputs, cycles, and joins. The practitioner is consequently empowered in exploring, reasoning with and validating their real-world models.

## 1 Introduction

A directed graph—or “digraph”—is a graph whose edges have direction and are called arcs [9, 11]. Arrows on the arcs are used to encode the directional information: an arc from vertex A to vertex B indicates that one may move from A to B but not from B to A. Such graphs for example are used in computer science as a representation of the paths that might be traversed through a program, or in higher-level conceptual models where concepts are related to each other by relations that gain additional semantics (i.e. meaning) by defining the direction between the source and target concepts. A classic illustration is a cat that sits on a mat [18]. In this simple example ‘sits-on’ is the semantic relation where the direction goes from cat to mat and not vice versa.

CGs (Conceptual Graphs) are digraphs that enable modellers to express meaning in a form that is logically precise whilst being humanly readable, and serve as an intermediate language for translating between computer-oriented formalisms and natural languages [14, 19]. CGs graphical representation thereby serve as a readable, but formal specification language for systems design or other practitioners using this approach [10]. CGs are however drawn by hand. Tools such as CoGui and CharGer already exist to assist the practitioner in creating a well-formed CG (Conceptual Graph) that adheres to the prescribed grammar and syntax [1, 2]. However there is no guarantee that a model created using CGs

is correct in terms of its validity. The modeller may have a misconception of the system being modelled or may simply make mistakes in its construction—things that still conform to the syntax and grammar but result in an invalid model.

It can be difficult to explore and validate a large and complex CG by inspection. It is this problem that this paper addresses by providing an automated method whereby key features of CGs are captured, reported and visualised. The modeller would thus be assisted in exploring and validating their CGs. The method makes use of the inherent direction of Concept-relation-Concept triples in CGs to transform these triples into binary relations and thus expose them to Formal Concept Analysis (FCA) [8]. The process is automated in a tool called *CGFCA* and has two stages; firstly parsing a CG file (in the ISO common logic *cgif* format [19]) to extract the CG triples and secondly, converting these triples into corresponding binary relations that accentuate the directed pathways in the original CG, as described next in Sect. 2. The triples-to-binaries function is carried out using an implementation of the *Triples2Binaries* algorithm, specifically described in Subsect. 2.2.

## 2 Transforming CG Digraphs: Triples into Binary Relations

If triples are extracted from a CG in the form *Source Concept*  $\rightarrow$  *relation*  $\rightarrow$  *Target Concept*, each such triple can easily be represented as a corresponding binary relation i.e. *Source Concept*-*relation*, *Target Concept*. Where the Target Concept then becomes a Source Concept for a following relation, this can be captured in additional binary relations, where the original Source Concept-relation is paired with subsequent Target Concepts. To illustrate the source-target structure, Fig. 1 shows a simple CG with the CG Concepts, [Cat], [Mat] and [Colour: Grey]. [Cat] and [Mat] are linked by the CG relation (sits-on) and [Mat], [Colour: Grey] are linked by (has-attribute). (In simple English, the CG describes a cat that sits on a grey mat.) We can say that the

Fig. 1. Simple CG

Fig. 2. FCL for simple CG

*target Concept* [Mat] is dependent on the *source Concept-relation pair* [Cat]  $\rightarrow$  (sits-on) and the *target Concept* [Colour: Grey] is dependent on its *source Concept-relation pair* [Mat]  $\rightarrow$  (has-attribute) (or alternatively, the *source Concept-relation pair* [Cat]  $\rightarrow$  (sits-on) results in the *target Concept* [Mat] and the *source Concept-relation pair* [Mat]  $\rightarrow$  (hasattribute) results in the *target Concept* [Colour: Grey]). The CG triple ([Cat], (sits-on), [Mat]) can be converted into the binary relation ([Cat]-(sits-on), [Mat]). Likewise the CG triple ([Mat], (hasattribute), [Colour: Grey]) can be converted into the binary relation ([Mat](has-attribute), [Colour: Grey]).

There is also a binary relation between [Cat] and [Colour: Grey] indirectly through [Cat]-(sits-on). Hence [Colour: Grey] also depends (indirectly) on [Cat], which is of course sitting on that mat.

Simple CG	Cat sits-on	Mat has-attribute
<i>Cat</i>		
<i>Mat</i>	×	
<i>Colour : Grey</i>	×	×

**Fig. 3.** The simple CG as a cross-table

The set of binary relations can be simply represented in a cross-table and Fig. 3 shows the corresponding cross-table for this simple example, with rows representing CG Concepts and columns CG Source Concept-relations. The cross-table is known as a Formal Context in FCA, so by converting CGs into these binary relations, FCA can then be applied. Figure 2 displays the resulting Formal Concept Lattice (FCL). This approach was derived after we compared it with Wille’s mapping of CGs to FCA (‘Concept Graphs’) in an earlier study [5, 20]. Figures 4, 5, and 6 show the CG, FCL and cross-table (Formal Context) for a larger CG using the same Cat on Mat example. Figures 7, 8, and 9 show the CG, FCL and cross-table for a further extended version of this example. This time it has two input CG Concepts, [Cat: Gwyn] and [Cat: Bumbles] thus depicting the specific cats Gwyn and Bumbles as the respective CG referent for each CG Concept as shown.

## 2.1 Obtaining Triples from a Conceptual Graph: A Parser for *cgif*

To automate this process, a parser was created that operates on the standard CG file format, *cgif*. To illustrate the format, below is the *cgif* for the ‘Cats on the Mat’ CG in Fig. 7:

```
[Material: Fleece] [Cat: Gwyn] [Mat: *x1] [Cat: Bumbles] [Colour: Grey]
(sits-on Bumbles Gwyn ?x1)(has-attribute Fleece Grey)(made-from ?x1 Fleece)
```

The first line in the *cgif* defines the CG Concepts and the second line defines the CG relations. In line with CGs theory where the referent is unknown, *cgif*

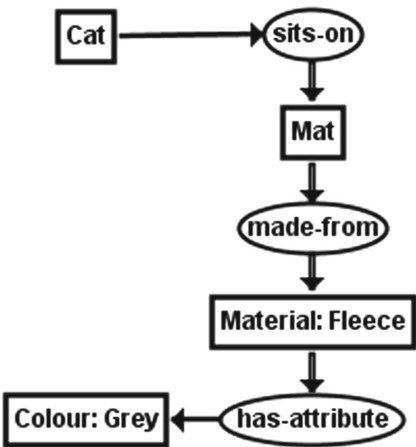

Fig. 4. CG with 4 concepts

	Mat made-from			
	Material: Fleece has-attribute			
Cat : Bumbles				
Cat : Gwyn				
Mat	×	×		
Material : Fleece	×	×	×	
Colour : Grey	×	×	×	×

**Fig. 9.** The 2 input CG as a cross-table

uses generic referents such as **x1** and **x2**, with a preceding **\*** (in CG Concepts) or **?** (in CG relations). Each relation is defined in the *cgif* with a list of referents comprising one or more source CG Concept referents and a target CG Concept referent. The final referent in the list is always the target referent. Thus, in the relation **made-from**, **x1** is the source and **Fleece** is the target, and in the relation **sits-on**, **Bumbles** and **Gwyn** are sources and **x1** is the target.

The parser first extracts the CG Concepts from the *cgif*, creating an integer index for each CG Concept and separating the type labels and referents (see Table 1a). The parser then extracts the CG relations from the *cgif*, creating an integer index for each CG relation and separating the type labels and lists of referents (see Table 1b).

**Table 1.** Information extracted by parser from Cats on the Mat *cgif*

No.	Label	Referent	No.	Label	Referents
1	Material	Fleece	1	sits-on	Bumbles Gwyn x1
2	Cat	Gwyn	2	has-attribute	Fleece Grey
3	Mat	x1	3	made-from	x1 Fleece
4	Cat	Bumbles			
5	Colour	Grey			

(a) CG Concepts

(b) CG relations

If there are co-referent CG Concepts or relations, the parser will form the corresponding joins. For CG Concepts, as each Concept label and referent is extracted from the *cgif*, the referent is compared to the list of Concept referents

already extracted. If a match is found, instead of adding a new Concept, the parser compares the two Concept labels. If they are different, it concatenates the new label with the existing label in the list, if not the parser simply moves on to the next Concept in the *cgif*. A similar process is carried when parsing the CG relations in the *cgif*, but here it is the list of referents associated with the relation that is compared: for two CG relations to be co-referent they must have the same sources and target. For examples of joining co-referents see Sect. 4.8.

Once the CG Concepts and relations have been extracted (and any co-referent joins made), the parser then uses the referents for each relation to create corresponding triples by looking up the index number of the relation's source and target CG Concepts corresponding to the relation's referents. Table 2 contains the triples created from Table 1. The triples thus created are now ready for the process of converting them to corresponding binary relations.

**Table 2.** Cats on the Mat triples

Source	Relation	Target

2	1	3
1	2	5
3	3	1

## 2.2 A Triples-to-Binaries Algorithm

Figure 10 is an algorithm, *Triples2Binaries*, that along with its subroutine *AddBinary* (Fig. 11), converts a set of triples,  $T$ , into a corresponding set of binaries,  $B$ , exploiting the direction in the triples as explained above. It is a generalised form of the *CGtoFCA* algorithm previously presented [5]. Whilst its application to CGs is the focus of this paper, the more general form makes it applicable to directed triples obtained from any source, including UML, RDF, OWL, the Entity-Relation Diagram and linked data. *Triples2Binaries* also includes some refinements not present in *CGtoFCA*, namely; the ability to detect 'direct pathways' and cycles in a CG. A direct pathway through a CG is a path from an input CG Concept to an output CG Concept, where an input CG Concept is one with no edges entering it and an output CG Concept is one with no edges leaving it. Features such as direct pathways and cycles often have significant meaning in a CG but are not always easily apparent (particularly in large CGs). The main algorithm, *Triples2Binaries*, simply iterates through the set of triples,  $T$ , sending each triple,  $(s, r, t)$  to the subroutine *AddBinary*. In  $(s, r, t)$ ,  $s$  denotes the *source*,  $r$  denotes the *relation* and  $t$  denotes the *target*. Each triple enumerated in *Triples2Binaries* will be the start of a new pathway. A pathway is recorded by *AddBinary* as a set of  $(source, relation)$  pairs in *path*.

*AddBinary* takes each triple  $(s, r, t)$ , adds  $(s, r)$  to the current path (line 2) and then adds the corresponding binary  $((s, r), t)$  to the set of binaries,  $B$  (line 3).

Line 4 is a test for detecting a direct pathway in the CG: if the current source,  $s$ , is an input CG Concept and the current target,  $t$ , is an output CG Concept, then there is a direct pathway from  $s$  to  $t$ . In which case, the current path along with  $t$  is recorded as a direct pathway.

Line 6 is the condition for detecting a cycle in the CG: if the current source,  $s$ , is the same as the current target,  $t$ , there is a cycle, recorded in line 7 as the current path along with the current target.

Line 8 defines the terminating condition for recursion (thus preventing infinite loops around cycles): if the current target,  $t$ , is already in the current path then *AddBinary* terminates. Otherwise, line 9 iterates through the set of triples,  $T$ , to test for links (line 10): if the current target,  $t$ , also appears as a source,  $i$ , in the set of triples, *AddBinary* is called recursively (line 11), passing the current source,  $s$ , the current relation,  $r$ , and the new target,  $k$ .

Note that the condition for a cycle (line 6) cannot be used as the terminating condition for recursion. This is because the starting point for a cycle can occur at any point in a pathway. A pathway begins with the source,  $s$ , and if the starting point of a cycle begins later than  $s$ , then  $s$  will never equal  $t$  and we would have an infinite loop around that cycle.

```

1 begin
2    $path \leftarrow \emptyset$ 
3   foreach  $(s, r, t) \in T$  do
4      $AddBinary(s, r, t, path)$ 
5 end

```

**Fig. 10.** *Triples2Binaries*( $T$ )

### 3 The CGFCA Tool

The *cgif* parser and *Triples2Binaries* algorithm were implemented together to form a software tool called CGFCA. The architecture of CGFCA is shown in Fig. 12. The *cgif* parser inputs a CG in the form of a *cgif* file and creates a corresponding set of CG (source Concept, relation, target Concept) triples as described in Sect. 2.1. The triples are then passed to Triples to Binaries which converts them into ((source Concept, relation), target Concept) binaries, including the computation of all binaries with indirect target Concepts, as described in Sect. 2.2. Triples to Binaries also carries out an analysis of the CG and reports the following features: input Concepts, output Concepts, direct pathways (from an input Concept to an output Concept), cycles and pathways with multiple routes (these are multiple pathways from the same input Concept-relation to the same output Concept). These multiple routes were considered worth detecting and reporting as they may indicate redundant pathways in a CG. The ((source Concept, relation), target Concept) binaries computed by Triples to Binaries

```

1 begin
2    $path \leftarrow path \cup \{(s, r)\}$ 
3    $B \leftarrow B \cup \{((s, r), t)\}$ 
4   if  $IsInput(s)$  and  $IsOutput(t)$  then
5      $RecordDirectPathway(path, t)$ 
6   if  $s = t$  then
7      $RecordCycle(path, t)$ 
8   if  $\neg \exists (x, y) \in path \mid t = x$  then
9     foreach  $(i, j, k) \in T$  do
10       if  $t = i$  then
11          $AddBinary(s, r, k, path)$ 
12 end

```

**Fig. 11.**  $AddBinary(s, r, t, path)$

are then passed to a simple Formal Context Creator where the (source Concept, relation) in each binary is treated as a formal attribute and each target Concept is treated as a formal object. The formal context is output in the standard *cxt* format for FCA.

**Fig. 12.** CGFCA architecture

The formal context output by *CGFCA* can then be visualised as a Formal Concept Lattice (FCL) using an appropriate tool, such as *ConceptExplorer* (*Con-Exp*)<sup>1</sup> or as a Formal Concept Tree using In-Close [3, 4]. Such visualisations clearly highlight further CG features such as cycles and co-referent joins.

<sup>1</sup> <http://conexp.sourceforge.net/>.

## 4 Highlighting Key Features of a CG Using CGFCA

This Section uses simple CG examples to illustrate the use of the GCFCA tool in detecting and highlighting features of CGs and how corresponding FCLs allow a GC to be explored in a formal, hierarchical, visualisation.

### 4.1 Paths and Dependencies

Figures 13 and 14 respectively illustrate the CG and FCL for the dependencies described earlier in a larger example—as well as two paths—between the source Concept [Person: Simon] and the target Concept [City: London]. As well as the intermediate target Concepts that in turn become source Concepts (i.e. [Coach: #564] and [Hotel: OpenSky]), this example shows CG referents, namely Simon, #564, OpenSky and London. ([Colour: Grey] from Fig. 2 was also a CG Concept with a referent.) The referents are instances of their respective type label in the CG Concept e.g. London is a referent of the type label City, and #564 the numeric identifier for a Coach that in the context of Fig. 13 could be read as the number of the coach that goes to London. In addition to the direct dependencies such as [Hotel: OpenSky] on [Person: Simon]-(books) there are indirect dependencies detected in accordance with *AddBinary* line 4 described earlier in Subsect. 2.2. These are: (a) [City: London] on [Person: Simon]-(books), and (b) [Person: Simon]-(travels-to) through the other path that has the intermediate Concept [Coach: #564]. The starting (or input) Concepts and ending (or output) Concepts are usefully reported by the *CGFCA* software i.e. Inputs: “Person: Simon”. Outputs: “City: London”. The output also states: Direct Pathway: Person: Simon - books - Hotel: OpenSky - location - City: London and Direct Pathway: Person: Simon - travels-by - Coach: #564 - destination - City: London.

Fig. 13. Paths and dependencies CG

Fig. 14. Paths and dependencies FCL

In simple terms, Simon's trip to London depends on travelling there by coach and booking into the OpenSky hotel. Of course in this still-simple example this knowledge can be gleaned from the CG alone thereby obviating the need for *CGFCA*. However it is more likely that these patterns will appear in larger CGs where it is not so evident, perhaps unknowingly as they are drawn by hand and obfuscated by the size of the larger model. *CGFCA* and the consequent computer-generated FCL will highlight within such digraphs the 'diamond' looking patterns that represent multiple pathways thus alerting their existence—hence validity—to the modeller.

## 4.2 Cycles

It is natural that digraphs may contain one or more cycles. Figures 15 and 16 respectively illustrate an example of a CG and FCL that is a cycle. Note that this example is similar to the previous paths and dependencies example in Figs. 13 and 14. This time the direction of the hotel booking path goes in the opposite direction, thus creating the cycle. The renaming of the relations i.e. *location* to *location-of* and *books* to *booked-by* correctly reflect the new direction. It is common however to name or use relations that cause cycles to occur inadvertently such as possibly in this example. A cycle may of course be desired, but the modeller will in any event be alerted to its validity by the FCL (here Fig. 16) in accordance with *AddBinary* line 7 described earlier in Subsect. 2.2. The *CGFCA* output highlights why the Fig. 16 lattice looks as it does: There are no inputs. There are no outputs. Cycle: City: London - location-of - Hotel: OpenSky - booked-by - Person: Simon - travels-by - Coach: #564 - destination - City: London. Every Concept is dependent on all the other Concepts with no hierarchy, thus they become grouped together in the FCL.

Fig. 15. CG that is a cycle

Fig. 16. FCL of cycle

### 4.3 Joins

Figures 17 and 18 respectively illustrate the CG and FCL for Concepts that are co-referent. Co-referents occur when Concepts have the same referent, which in this case is *Gwyn* in *Pet* and *Cat*. Where a source and target Concept are directly linked by more than one relation, the associated relations are in effect co-referent. This behaviour is highlighted by Figs. 19 and 20.

Fig. 17. CG with co-referent concept

Fig. 18. FCL with co-referent concept

Fig. 19. CG with co-referent relations

Fig. 20. FCL with co-referent relations

Before the *Triples2Binaries* algorithm in *CGFCA* is called, the *CGFCA cgif* parser detects co-referent CG Concepts and co-referent CG relations and because they refer to the same object or instance it joins the Concepts and relations automatically (see Sect. 2.1). Furthermore it concatenates the Concept type or relation labels, using ‘;’ as the delimiter.

The outcome is evident in the FCL for Figs. 18 (i.e. *Pet;Cat*) and 20 (i.e. *sleeps-on;sits-on;prefs*). This approach is akin to the maximal common subtype in CGs (or intersection); thus *Gwyn* is (a) a *Pet Cat*, and (b) *sleeps, sits on, and likes the Mat*<sup>2</sup>.

A common error (particularly in larger or more complex models) is to give different types the same referent by mistake. Take for example the CG Fig. 19.

<sup>2</sup> Note *Mat* here has a latent referent, in accordance with CGs theory; hence we can simply refer to it through the definite article ‘the’.

In that Figure let's change [Mat: Gwyn's] to [Mat: Gwyn], assuming that it was mistyped by the modeller in the first place. As a result, [Mat: Gwyn] will inadvertently join with the [Cat: Gwyn] and [Pet: Gwyn] CGs from Fig. 17. Figure 21 shows the CGs for this scenario including the mistake, and Fig. 22 demonstrates the result. Now Gwyn is not only a Pet Cat but a Mat too! And Bumbles sleeps-on, sits-on and prefers Gwyn as a Mat (rather than Gwyn's Mat) while Gwyn sits on another Mat, all of which is nonsensical as the FCL reveals. Like the previous pathways and cycles examples, the practitioner is immediately presented with a need to reason with and validate their models.

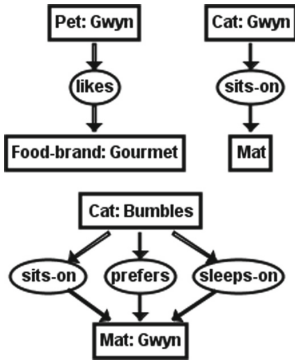

Fig. 21. CG with co-referents

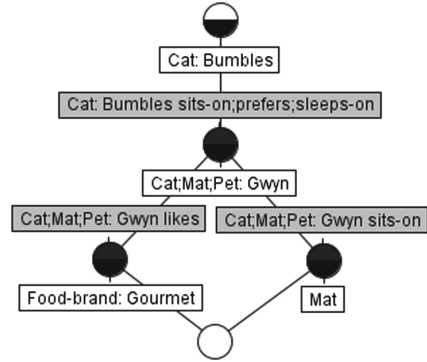

Fig. 22. Mistakenly joined CGs FCL

#### 4.4 *n*-adic

Apart from Fig. 7 earlier, the CG relations so far have been *2-adic* i.e. only one source CG Concept pointing to the relation. *2-adic* CG relations are also known as *dyadic* CG relations. A CG relation may however have more than one source CG Concept; hence an *n*-adic CG relation has *n* source CG Concepts. The CG relation *sits-on* in Fig. 7 is *3-adic*, or *triadic*.

Figures 23 and 25 highlights the relation *sits-on* being stated as being dyadic or triadic respectively. CG relations may any number of source CG

Fig. 23. CG with 2-adic relation

Fig. 24. FCL with 2-adic relation

Fig. 25. CG with 3-adic relation

Fig. 26. FCL with 3-adic relation

Concepts pointing to them<sup>3</sup>. Figures 24 and 26 reveal that the FCL for Figs. 23 and 25 turn out to be identical, thus two representations of the same meaning. Unsurprisingly, the *CGFCA* output is identical for both the 2-adic and the 3-adic: Inputs: "Cat: Gwyn" "Cat: Bumbles" Outputs: "Mat: Gwyn's" Direct Pathway: Cat: Gwyn - sits-on - Mat: Gwyn's Direct Pathway: Cat: Bumbles - sits-on - Mat: Gwyn's.

Certain CG relations such as '(share)' inherently can only have certain n-adic values. For the **share** case, there need to be two or more things to have something shared between them, hence **share** has to be at least triadic i.e.  $\geq 3$ -adic. As *CGFCA* would provide the same outcome even if the **share** CG relation was modelled as dyadic accidentally by the modeller, it would still be correctly depicted in the FCL. For completeness, Figs. 27, 28, 29 and 30 respectively demonstrate this outcome.

Fig. 27. CG, 'wrong' 2-adic share

Fig. 28. FCL, 'corrected' share

Fig. 29. CG, 'correct' 3-adic share

Fig. 30. FCL, 'correct' 3-adic share

<sup>3</sup> CG relations may however have only one target CG Concept [17].

### 4.5 Formal Concepts Without Their Own Attributes or Objects

Unlike the examples shown thus far where it has only occurred at the bottommost (or *infimum*) Formal Concept in an FCL, CGs may generate an FCL that has Formal Concepts without their own attributes (i.e. *Source Concept-relation*) or objects (i.e. *Target Concept*) in the middle of the FCL. Figure 31 has generated such a formal concept as evident in Fig. 32.

Essentially this is because [Cat: Bumbles] and [Cat: Gwyn] *both* sit-on the [Mat: Gwyn's] *and* have the heritage of [Pedigree: British\_Blue]. This pattern can be gleaned from the corresponding *CGFCA* output for Figs. 31 and 32:

Inputs: "Cat: Bessie" Outputs: "Mat" "Pedigree: British\_Blue"

Direct Pathway: Cat: Bessie - offspring-of - Cat: Bumbles - heritage - Pedigree: British\_Blue

Direct Pathway: Cat: Bessie - offspring-of - Cat: Bumbles - sits-on - Mat

Direct Pathway: Cat: Bessie - offspring-of - Cat: Gwyn - sits-on - Mat

Direct Pathway: Cat: Bessie - offspring-of - Cat: Gwyn - heritage - Pedigree: British\_Blue

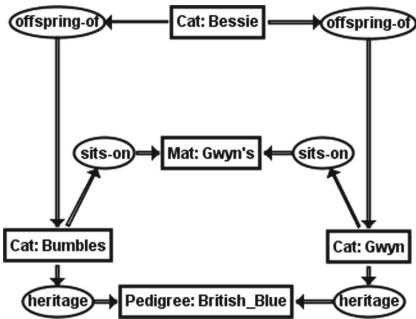

Fig. 31. CG leading to unlabelled FC

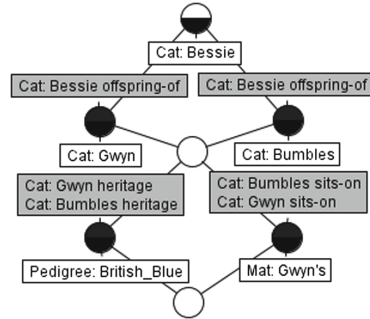

Fig. 32. FCL with unlabelled FC

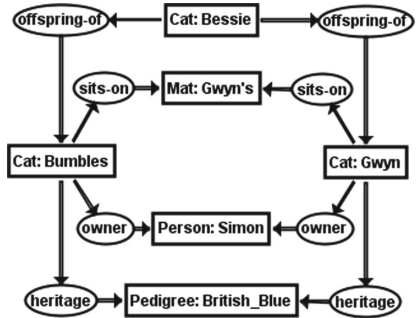

Fig. 33. Larger CG, unlabelled FC

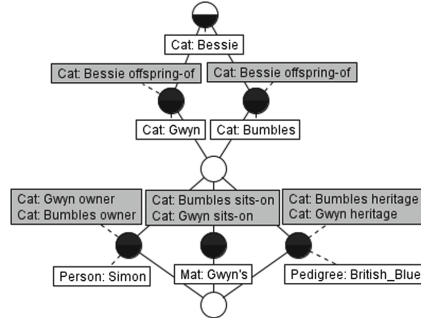

Fig. 34. Larger FCL, unlabelled FC

The only way to traverse the FCL to capture these relations is through the unlabelled Formal Concept in between.

Figures 33 and 34 evidence the pattern in a larger example where, essentially, [Cat: Bumbles] and [Cat: Gwyn] *both* sit-on the [Mat: Gwyn's] *and* have the heritage of [Pedigree: British\_Blue], *and* have as their owner the [Person: Simon]. The *CGFCA* output underpins the pattern:

Inputs: "Cat: Bessie" Outputs: "Person: Simon" "Mat: Gwyn's" "Pedigree: British\_Blue"

Direct Pathway: Cat: Bessie - offspring-of - Cat: Bumbles - owner - Person: Simon

Direct Pathway: Cat: Bessie - offspring-of - Cat: Bumbles - heritage - Pedigree: British\_Blue

Direct Pathway: Cat: Bessie - offspring-of - Cat: Bumbles - sits-on - Mat: Gwyn's

Direct Pathway: Cat: Bessie - offspring-of - Cat: Gwyn - heritage - Pedigree: British\_Blue

Direct Pathway: Cat: Bessie - offspring-of - Cat: Gwyn - owner - Person: Simon

Direct Pathway: Cat: Bessie - offspring-of - Cat: Gwyn - sits-on - Mat: Gwyn's.

#### 4.6 Further Exploring $n$ -adity

For Fig. 33 we can also identify the presence of 3-adic (triadic) relations, as CG Fig. 35 reveals. Note once more that the FCL Fig. 36 is identical to Fig. 34.

Figure 37 has a CG with *heritage* as a 4-adic relation, essentially adding that [Cat: Bessie] has the heritage of [Pedigree: British\_Blue] too, along with [Cat: Bumbles] and [Cat: Gwyn]. Through the unlabelled Formal Concept the 4<sup>th</sup> adic is highlighted by Fig. 38.

#### 4.7 Further Exploring Co-Referent Links

Figure 37's CG can be restated using a co-referent link as shown by Fig. 39. In this Figure, the CG Concept [Pedigree: British\_Blue] appears twice. Note also that the 4-adic *heritage* relation has disappeared, or so it would appear?

Fig. 35. Same CG, 3-adic

Fig. 36. Resulting same FCL

Fig. 37. CG, with 4-adic

Fig. 38. FCL, with 4-adic

Fig. 39. Same CG, but co-referent

Fig. 40. Resulting same FCL

Note that Fig. 40, which is the FCL for Fig. 39 is identical to the FCL Fig. 38. The *CGFCA* parser applies the CG join operation as before thus causing the co-referents—as they are the same CG referent—to be joined [14, 17, 19]. The significance of this example is that it reminds us that CGs may be hand-drawn in different ways (e.g. different adity, or using co-referents advertently—or inadvertently as we saw with [Mat: Gwyn] in CG Fig. 21 and the corresponding FCL Fig. 22). However the FCL will represent them in *one* way, thus potentially removing multiple, and potentially confusing ways of stating the same thing differently.

#### 4.8 Larger Joins

Lastly to illustrate the wider behaviour of digraphs through CGs the above-discussed examples are essentially joined into one CG. Figure 41 shows the result of joining the other CGs (except Fig. 15) with Fig. 13, which showed the dependency from [Person: Simon] to [City: London] *without* the cycle, whereas Fig. 42 shows the result of joining the other CGs (except Fig. 13) to Fig. 15, which showed [Person: Simon] to (and from) [City: London] *with* the cycle.

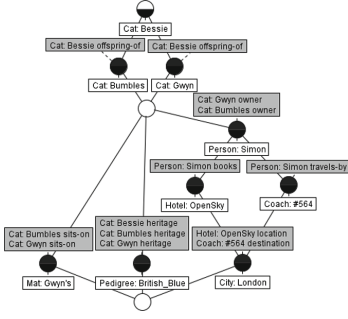

Fig. 41. Joined FCL no cycle

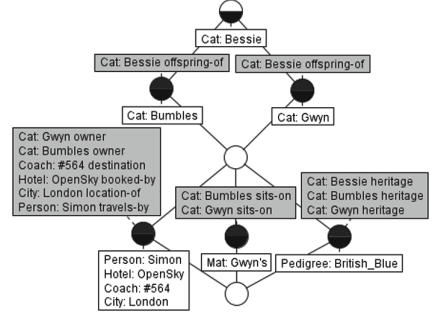

Fig. 42. Joined FCL with cycle

## 5 A Realistic Example

The simple but expressive examples presented thus far demonstrate how digraphs can be explored and validated through *Triples2Binaries* as exemplified by *CGFCA*. Previous work has indicated *CGFCA*'s value in the business information systems modelling domain [15]. Based on an example from that work, a more comprehensive example is now presented from that real-world domain. Whilst the example uses the terminology of that domain, this example will be explained such that it can be more widely understood.

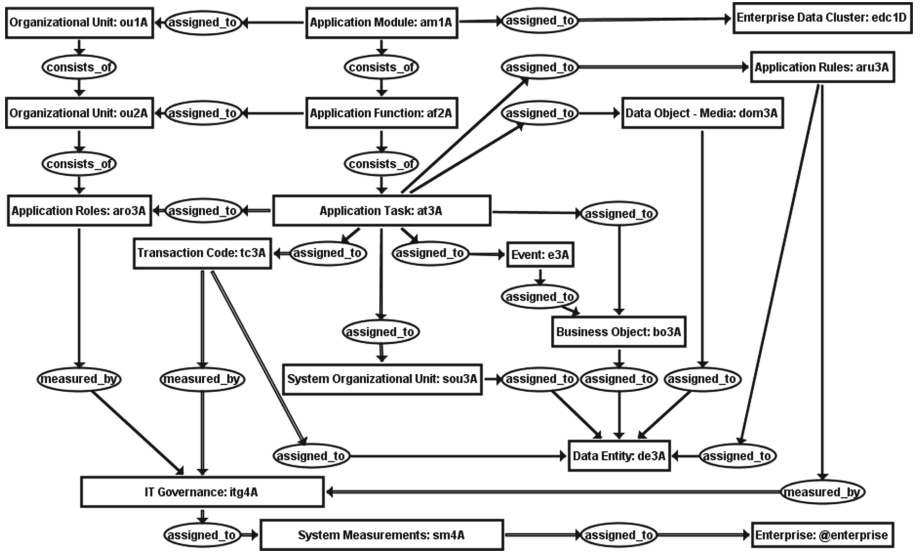

Fig. 43. Application module CG

As explained from the outset, human modellers draw diagrams to elicit the dimensions of some problem that becomes too difficult to understand through discursive narrative alone. We have seen that through CGs, the directed graph (digraph) offers the significant advantage of capturing the directional information i.e. an arc from vertex A to vertex B indicates that one may move from A to B but not from B to A. As well as their use in computer science as a representation of the paths that might be traversed through a program, the examples demonstrate digraphs' applicability in higher-level conceptual models where concepts are related to each other by relations that gain additional semantics (i.e. meaning) by defining the direction between the source and target concepts.

CGs (Conceptual Graphs) are an expressive form of digraphs that enable modellers to express meaning in a form that is logically precise whilst being humanly readable. As such, they provide a conceptual structure that can formally describe the given problem being modelled. CGs, in common with many other forms of diagrams are however drawn by hand, even with the assistance

of software tools such as CoGui suggested earlier [2]. Currently, the modeller enters the digraphs—in this case CGs—into the tool manually and relies on the tool to work with the potentially erroneous CGs entered into it. In effect the tool is as only as good as the fool that uses it, so “a fool with a tool is still a fool”—a common criticism from industry [12]. While a business (or other) modeller may be no fool, there is no guarantee that a model created using CGs is correct in terms of its validity. In their exploration of the given problem using CGs, the modeller may have a misconception of the system being modelled or may simply make mistakes in its construction—things that still conform to the syntax and grammar but result in an invalid model. The current situation is too complicated, and presents an unwarranted burden on the modeller.

Formal Concept Analysis (FCA) claims to add mathematical rigour to the logical rigour captured in CGs [10]. *CGFCA* reveals FCA’s effectiveness in this respect, thereby moving away from the current situation with its unnecessary complications as described above. We now further test this effectiveness using business modelling as the more comprehensive illustration.

## 5.2 Understanding the Complications

The CG Fig. 43 describes the components of a software application module that is part of an information system in an organisation. Applying *CGFCA* as above, Fig. 44 is the corresponding FCL for this CG Figure. The human business modeller draws this CG to capture the entities as CG Concepts and the CG relations between them. The detailed meaning of each entity and relation is discussed elsewhere [15], but for the purposes of our understanding the application module is denoted by the CG Concept: [Application Module: am1A]. The referent ‘am1A’ uniquely identifies the application module. The remaining CG Concepts and relations flow down from [Application Module: am1A]. This is validated by Application Module: am1A being at the supremum (topmost) Formal Concept of the lattice, Fig. 44. The modeller requires each referent throughout this CG to be unique and have no cycles in it. Figure 44 evidences that the Application Module as a CG is accurately captured. In practice this is unlikely to be the case. What are the complications in drawing the model that can undermine its validity, and how are these complications revealed by *CGFCA* and the lattice?

**Arrow Direction.** A common mistake or misconception that a modeller can make is to draw the arrows the wrong way round. This is a complication that may seem obvious on close inspection of the CG but nonetheless easily occurs even in introductory CGs despite proof-checking [14]. The syntax of the CG is correct—i.e. it is still a digraph (directed graph)—but this act results a semantic error. Figure 46, which is an extract of the lattice for the CG Fig. 45 shows that Application Module: am1A is not at the supremum; its place is taken by Organizational Unit: ou1A. This change of input is also shown by the *CGFCA* report: Inputs: “Organizational Unit: ou1A”. The modeller is alerted to this deficiency because the arrows between [Application Module: am1A] and

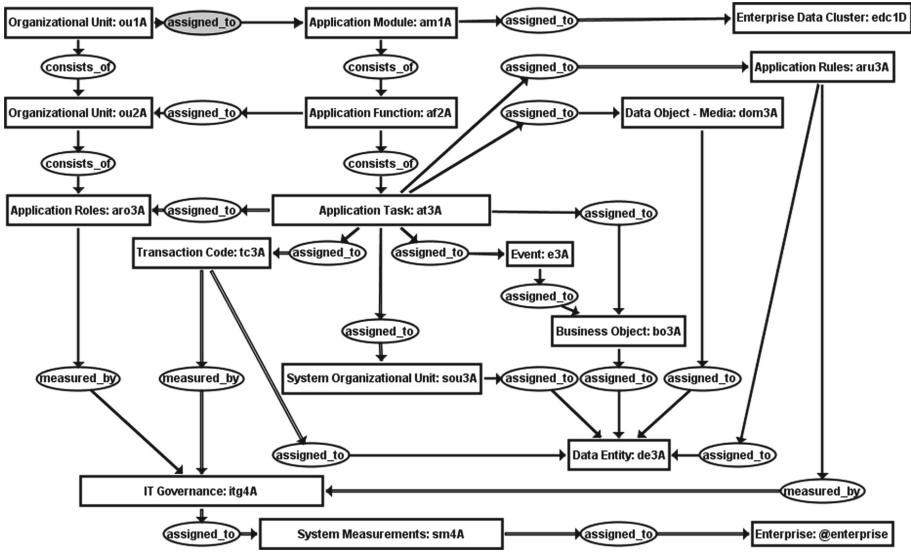

Fig. 45. Application module CG, wrong arrow direction

Fig. 46. Application module FCL extract, wrong arrow direction

[Organizational Unit: ou1A] in CG Fig. 45 were accidentally drawn the other way, unlike in the correctly-drawn previous CG Fig. 43. The modeller can then correct the model. The modeller may want to manually record the mistake for future reference, by shading the ‘offending’ (assigned\_to) CG relation as shown in Fig. 45.

**Mispointed Arrows.** The CG Fig. 47 highlights another common mistake (or misconception) where a CG relation is pointed to the wrong CG Concept. In this case it’s [Transaction Code: tc3A] → (assigned\_to) → [IT Governance: itg4A]. It should be [Transaction Code: tc3A] → (assigned\_to) → [Data Entity: de3A]. For convenience the offending relation is highlighted in Fig. 47. In practice the modeller would run *CGFCA* then generate the FCL (of which Fig. 48 is an extract) before highlighting the incorrect CG. From FCL Fig. 47 the modeller notices that assigned\_to;measured\_by is incorrectly concatenated in Transaction Code: tc3A assigned\_to;measured\_by.

Fig. 47. Application module CG extract, assigned\_to mispointed

Fig. 48. Application module FCL extract, assigned\_to mispointed

Such concatenations were demonstrated earlier by the FCL Fig. 20 (i.e. *Cat: Bumbles sleeps-on;sits-on;prefers*), which was correct in CG Fig. 19 but incorrect in CG Fig. 47. Again a close inspection of CG Fig. 47 would reveal this complication, but it can easily happen in practice.

**Unwanted Cycles.** While cycles may be deliberate, in many cases including this business modelling scenario they point to a mistake or misconception. That is the case of the CG Fig. 49 that emerges in the FCL of which Fig. 50 is an extract. The cycle is still rather subtle however as the FCA attributes *Business Object: bo3A assigned\_to*, *Event: e3A assigned\_to* and *Application Task: at3A assigned\_to* are spread across two Formal Concepts before the FCA objects

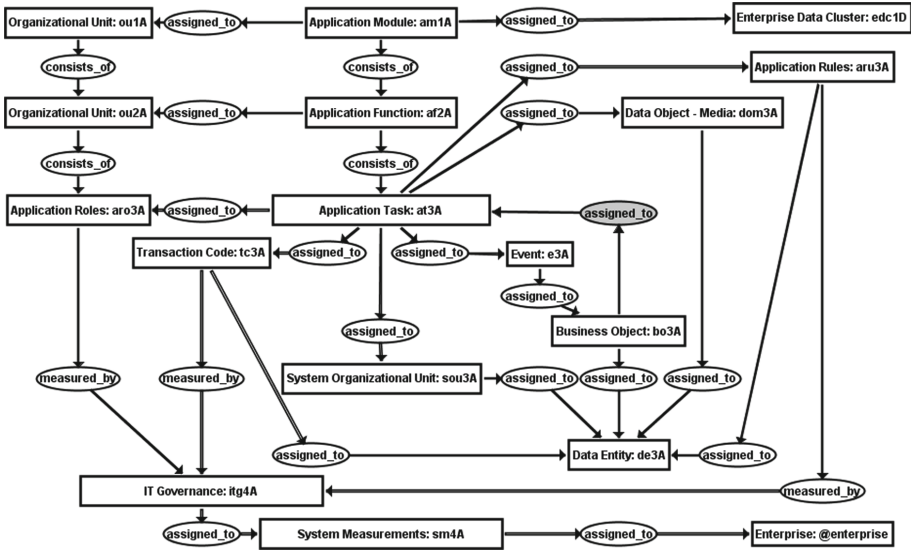

Fig. 49. Application module CG, cycle

Fig. 50. Application module FCL extract, cycle

Business Object: bo3A, Event: e3A assigned\_to and Application Task: at3A are reached showing that the CG Concepts in the attributes (eventually) point to themselves as the CG Concept denoted by the FCA object. The *CGFCA* report brings it most easily to light:

Cycle: Application Task: at3A - assigned\_to - Event: e3A - assigned\_to - Business Object: bo3A - assigned\_to - Application Task: at3A.

The FCL is nonetheless of value as the Formal Concept that has the three attributes listed above (i.e. Business Object: bo3A assigned\_to, Event: e3A assigned\_to and Application Task: at3A assigned\_to) doesn't have its own object (i.e. target CG Concept). This is highlighted by the bottom half of this Formal Concept's circle being transparent due to the other dependencies in the FCL. The modeller sets those other dependencies aside, as (s)he has identified that the unwanted cycle is the issue and its correction may also resolve any other suspect dependencies (which it does). The cause? That common error of a relation with the arrows pointing the wrong way i.e. the (assigned\_to) CG relation that points to [Application Task: at3A] from [Business Object: bo3A] when the CG relation should be the other way round. This time it causes a cycle as a revisit to the CG Fig. 49 and following this CG relation—using the *CGFCA* report as our guide—brings the cycle to light. For the record, the offending (assigned\_to) is shaded in the CG Fig. 49. The cycle in the FCL Fig. 50 is also highlighted by the rectangles with thick black borders.

**Invalid CG Referents.** Remember in Fig. 22 i.e. Cat;Mat;Pet: Gwyn, Gwyn became not only a Pet Cat but a Mat too! This common error appears in the CG Fig. 51 and becomes evident in FCL Fig. 52, where [Application Roles: ar3A] and [Application Rules: ar3A] accidentally share the same referent (ar3A); an easy error to make especially as the CG Type Labels Application

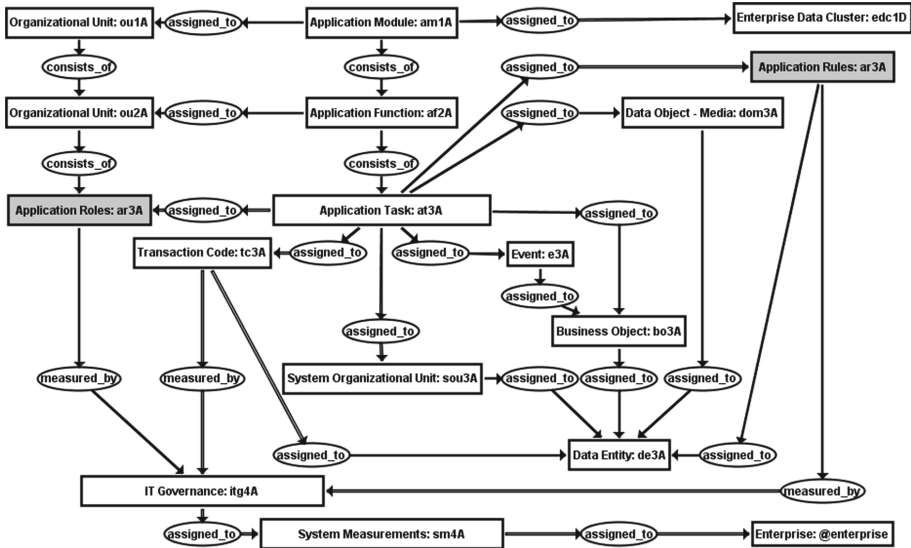

Fig. 51. Application module CG, ar3A referent

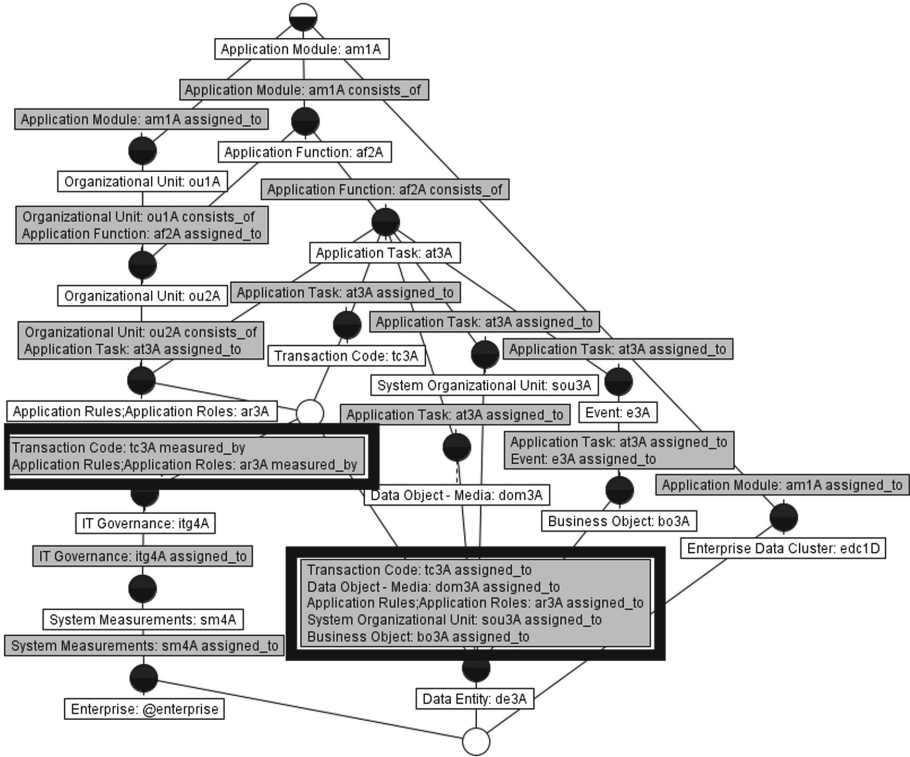

Fig. 52. Application module FCL, ar3A referent

Rules and Application Roles look so similar too! In the FCL Fig. 52 they are shown as **Application Rules; Application Roles** and, for emphasis, highlighted in thick black border rectangles. Likewise, and as before, the modeller in CG Fig. 51 shades these offending CG Concepts.

### 5.3 Resolving the Complications

While the above complications are not exhaustive, and not accounting for combinations of complications that could be further highlighted by the approach described, we have evidenced through the real-world scenario of business modelling how the human modeller as a practitioner (business or otherwise) is empowered by *CGFCA* and the FCL. In the course of this approach the modeller was able to explore the CG models, apply his/her reasoning from identifying issues in the models, thus leading to their correction. Through resolving the complications, the modeller acts as a human co-creator with the computer-generated *CGFCA* reports and FCLs (Formal Concept Lattices) thereby being empowered to produce useful, validated models.

## 6 Related Work

*CGFCA* originated with a comparative study to Wille's Concept Graphs as stated earlier, revealing the comparative advantages of *CGFCA* [5, 20]. *CGFCA*—hence *Triples2Binaries*—is however now at a level of maturity that it can play a useful role whilst recognising the existence of other FCA approaches to triple-based structures, such as Relational Concept Analysis (RCA), EL-Implications and Graph-FCA [6, 7, 16]. Extensive comparative studies in this arena already exist, pre-*CGFCA* [13]. While *CGFCA* fulfills the scope of our study, there is value in a up-to-date comparative study that includes *CGFCA*. Such work may help to identify how all the approaches may best work together for directed graphs and FCA.

## 7 Concluding Remarks and Further Work

As well as providing the capability to explore, reason with and validate directed graphs (digraphs), the FCL representation of CGs are arguably more readable. As we have seen, the arcs (the arrows) in a CG can lead in any direction. In a large, complex CG it can be difficult to trace and compare pathways through it, even more so where there are co-referent links. All FCL pathways are aligned in a top-to-bottom (inputs to outputs), hierarchical manner and co-referents can be automatically joined to make more apparent their connections and place in the graph.

Future work will continue to develop representative exemplars; a worthwhile endeavour given the value demonstrated by this paper. Furthermore since we have set the context as exploring and validating digraphs through triples to binaries rather than just CGs, the further work intends to include directed triples modelled by practitioners in UML, RDF, OWL, the Entity-Relation Diagram and linked data as alluded to earlier.

Meanwhile we have demonstrated that *CGFCA*—hence *Triples2Binaries*—presents a formal method that exploits CGs as digraphs through the application of Formal Concept Analysis (FCA). FCA elucidates key features of CGs such as pathways and dependencies, inputs and outputs, cycles, and joins. Given the prevalence of digraphs, the practitioner is consequently empowered in exploring, reasoning with and validating their models in understanding real-world phenomena.
