INTRODUCTION

Since the Bosman ruling in 1994, research has been undertaken around the various pieces of legislation designed to influence player development and recruitment (for example, Bullough and Mills, 2014; Radoman, 2015; Marcén, 2016). Other studies have developed the narrative around player migration patterns and national origin (Bond et al, 2016; Vaeyens et al, 2005), and demonstrated that the global nature of European football has increased substantially (Poli et al 2016; Richardson et al, 2012; Bullough et al, 2016). This is alongside the increasing role of global networks of agents, owners and others with a vested interest in elite football (Bond et al., 2016; Rossi et al, 2016).

Since the Bosman ruling, additional legislation has been introduced in the game which has sought to change the landscape of the way clubs operate. The Union of European Football Association (UEFA) home-grown quotas (influencing player development and player migration) were put in place from 2006-07 (UEFA, 2005) and Financial Fair Play rules were introduced in 2010 (Dermit-Richard et al, 2017). UEFAs home-grown regulation was endorsed by the European Parliament (Freeburn, 2009), with an aim to influence clubs' approach to youth development and opportunity across the European leagues. The rule places quotas on clubs to include a proportion of 'locally trained players' in their squad, although nationality is not the determining factor of 'locally trained'. The rule is based on the nationality of the club through which players have developed between the age of 15 and 21 (UEFA, 2005). Eight home grown players must be included in a squad of 25, with at least four 'club-trained' and four 'association-trained' (Dalziel et al, 2013).
Clubs' approach to meeting quota regulations is a key indicator of the efficacy of the rule, and research in this area is developing. With this in mind, this paper has three aims; (1) to examine the player production data from leagues and individual clubs across six European leagues in ten seasons (i.e. between 2006-07 and 2015-16) since UEFAs legislation began. The extent to which organisational structure influences player development is also an important element of the supply line (Relvas et al, 2010). Therefore the second aim (2) is to investigate the role that league structure plays in terms of player development 'outputs'. This is achieved by analysing the data of national associations' depending on whether they accept or prohibit second teams in their professional pyramid, as this differs by nation. The final aim of the paper (3) is to discuss the design of UEFAs legislation in terms of programme theory; examining UEFAs expected outcomes against what has happened. Whether the activities observed would have taken place without UEFAs intervention is also discussed.

The study replicates the methodology, timeframe and categories applied in a study focussing solely on England (Bullough and Jordan, 2017) and includes those players making their debut since 2005-06. The sample includes the 'big 5' leagues of England, France, Germany, Italy, Spain (Littlewood et al, 2011). The Netherlands are included to make a six league comparison as it has been a prominent producer of young players (Bullough et al, 2016).

**LITERATURE REVIEW**

Elite European football attracts global interest and investment, and the volume of playing opportunities for young indigenous players is an issue at the forefront of the ruling bodies' priorities. The legislative regulations introduced by UEFA around
playing opportunities, particularly in the last twenty years, have resulted in an enhanced focus on player opportunity. The legislation demonstrates this is a priority area of their mandate to govern the European game. However, exercising power in complex structures is notoriously difficult (Houlihan and Green, 2009). It has been cited that transfers have becoming more frequent and more complicated than at any time in history (Menke, 2014), and the recruitment of youth players from across the world has also increased significantly (Bond et al, 2016; Littlewood et al., 2011). The competitive nature of European leagues has also been shown to differ significantly (Ramchandani, 2012) with the 'big 5' leagues found to be the most competitive (France 1st, England 2nd, Spain 3rd, Italy 4th, Germany 6th) and this intensity of competition can have ramifications for recruitment and development strategies within clubs.

The Football Observatory (Poli et al, 2015) outlined a snapshot of playing data for July to October 2015 and found Spain was the only league of the main five in Europe where the percentage of club-trained players was over 20% at the start of the 2015-16 season. Clubs from these five leagues were also less likely to play their own club trained players; only three clubs had players playing more than 50% of the minutes available. This analysis by the Football Observatory provides an insight into the issue of player opportunity at the elite level of European football. This, however, is achieved using a cross-sectional rather than a longitudinal perspective, which demonstrates a snapshot rather than developing a greater depth of understanding.

Bullough and Jordan (2017) examined the quantity of English player outputs through the academy system in the ten seasons since UEFAs intervention in 2006. They looked at the clubs which produced players, where the players played, and how much they
played. The results outlined that the more established clubs (i.e. those ever-present in
the Premier League since 2006) had a modest output (141 of the 369 players produced)
and those players were likely to leave these clubs and play at lower achieving clubs (in
terms of league position). This study outlined a level of understanding around the
player development structure in England, however in order to provide greater
understanding around UEFA's rule, a wider scope is required to include the other main
European leagues.

Previous authors have identified that Spain, Netherlands, Germany and France have
recorded a greater level of appearances and minutes played for their indigenous
players, with England and Italy falling behind (Bullough et al, 2016). In addition,
England has been a prominent destination for migrating players both established, via
transfers, and through the youth academy system, (Bond et al, 2017; Poli et al, 2016).
Studies have also identified some of the developmental consequences of the Bosman
ruling in different European countries. For example Littlewood et al. (2011) outlined
an increase in non-indigenous players from 2005-2009 in the 'big 5' leagues; a decline
in the number of Spanish players was cited by Marcén (2016); a long-term decline in
indigenous playing opportunities was cited in England (Bullough and Mills, 2014);
and a high proportion of non-indigenous players in Italy (CEIS, 2015; Della Torre,
2017).

League Structure

European football is structured in a similar way at the elite level, in that most clubs
compete in similar sized leagues (n=18-20), with promotion and relegation present,
and an allocation of qualification entries for European club competitions (Champions
League and Europa League). This means comparing leagues, and clubs within those leagues, is possible as they are similar in their composition, structure and access to European competition. Despite this, there are differences across the major leagues with regard to the organisational structure and composition of tiered leagues underneath the top division, depending on the rules of that national association. The main difference between associations is the allowances made (or prohibition of) elite clubs' reserve teams (also referred to as 'amateur', 'B', 'II' teams) to play within the same structure as the first team. Within the six major European leagues, four allow it (Spain, Germany, France and Holland); four Spanish clubs also have a third team. Clubs are subject to limits regarding the highest tier of the league pyramid their second team can compete at; Spain (third tier); Netherlands (second tier); France (fourth tier); Germany (third tier).

England and Italy do not permit teams to have second teams competing in their league structure. England has 92 league clubs in four tiers, and some additional professional clubs in tier five. For second/reserve teams, England has a Premier League 2 competition for under 23s outside of the league pyramid, although as part of an FA initiative, Premier League teams are permitted to enter under 23 teams in the lower-league 'Check-a-Trade' Trophy. Italy has the Campionato Nazionale Primavera which is a youth competition comprising teams from Serie A and Serie B, for players aged 15 to under 19. Up to four "non-quota" players, limited to one with no age limit, are permitted. Alongside the overall analysis by country and by club, the above dichotomy between league structures forms part of the results section.

Philosophy and culture; influencing player development and recruitment
Previous studies have demonstrated different attitudes towards organisational culture between nationalities or clusters of nationalities. Giulianotti and Robertson (2009) outlined that football is a blend of intricate and overlapping influences from history, culture, politics, economics and society. The influence of nationality on organisational values/value systems was cited by Hofstede (1980) and developed further to place culture and values as important influences on behaviour. The relevance of cultural environment as an influencer on attitudes and behaviour was discussed by Ronen and Shenkar (1985) and this included clusters of nations based on variables such as the values, attitudes and goals of society. In this study, five of the nations included in the sample were cited but placed in three different clusters; Germany (Germanic cluster), England (UK) (Anglo cluster) and Spain, Italy, France (Latin European). Such studies outline clear differences between clusters in terms of culture and behaviour within organisations, and this cultural outlook may influence how individual clubs within these countries approach player development. Coyle (2018) proposed that culture in organisations is fashioned through everyday life, and the decisions taken reveal its identity and bias, which continually test the preferences of its leaders against reality.

Webb & Thelwell (2015) note commonly held beliefs around the different styles of play identified between different leagues, for example more physical and faster in England, a more technical approach based on skill and flair in Spain and a slower tactical construction of play in Italy. Such approaches may resonate with styles of play, links to national, regional or individual club culture, and changes in ownership. All are notable examples of different cultures and behaviours exhibited in clubs, in leagues and by individuals. There are some notable examples which outline some of the contrasting approaches clubs adopt towards player development and recruitment.
The influence of cultural identity on player behaviour is also important. Studies have shown that certain behaviours and specific traits can be attributable to players from certain countries (Webb & Thelwell, 2015), and this may include gamesmanship (Triviño, 2012; Berman, 2011) simulation (Renden et al., 2014) or introducing deception in a penalty kick (Dicks et al., 2010).

Examples show how the culture and approach to club operations differs between, and within, nations. Culture within some clubs is rooted in history, with some leading European clubs established at the end of the 19th Century, for example Manchester United (1878) and Barcelona (1899). Some elite clubs are much more recently established, such as RB Leipzig (formed in 2009). Different clubs have demonstrated a different standpoint around the inclusion of non-indigenous players in their first-team across the history of the game. This issue is also not a new phenomenon, as the formation of Internazionale Milan in 1908 shows (Facchetti and Zanetti, 2018). A disagreement between the owners of the Milan Cricket and Football Club (now A.C. Milan) around fielding players from overseas culminated in a split and the creation of a new club (Internazionale Milano). The new club name was derived from the founding members' willingness to include foreign players, demonstrating conflicting approaches in this area over 100 years ago.

One notable club in this regard is Athletic Club Bilbao, owned by its members with a (non-written) policy requiring players to be native to the Basque country; where profits are re-invested into the academy system (cantera) underpinned by a philosophy of 'con cantera y afición, no hace falta importación' meaning 'with home grown talent
and local support, you do not need imports' (Vaczi, 2015). The focus and resources are placed into sourcing and developing local talent rather than importing them. Athletic Club have a direct supply line into their first team through two routes; fourth tier feeder club CD Basconia and second/third tier Athletic Bilbao B, which are all part of the club structure. The strategy is for players to develop through the feeder teams before making the transition to the first team, which underpins their cultural identity.

FC Barcelona has the prominent 'La Masia' academy which has seen a stream of players graduate into the first team (Hunter, 2012). The identity created by Barcelona at organisational level (a collective sense of being, and knowing what the clubs stand for) is a shared concept across the playing staff, management, and club employees, known as 'més que un club' / more than a club (Harvard Business Review, 2015). Ajax Amsterdam are another notable club (producing esteemed players, van Basten, Bergkamp, Davids, Kluivert, Sneijder), but with a differing approach to retention. The majority of players are sold at a relatively young age for significant transfer fees, which is re-invested in the academy.

A divergent approach to youth development is Chelsea in England, particularly their use of the loan system. In 2016-17 the club had 36 registered players out on loan in addition to their first-team squad (Guardian, 2016; Independent, 2017). Chelsea have also recorded high value player sales for players that have played little for the club or been developed elsewhere. Two notable examples include Romelu Lukaku (purchased for £10m, 10 Premier League appearances for Chelsea in four years, two loans, sold for £28m); and Thibaut Courtois, purchased then loaned straight to Atletico Madrid for three seasons to develop, making 111 league appearances before returning to
Chelsea's first team in 2014. This organisational approach is in stark contrast to the
philosophy at some other clubs, but has either generated significant commercial
returns for players not breaking through for Chelsea or allowed other clubs to develop
their players ready for Chelsea's first team. These examples demonstrate the more
extreme (and contrasting) operating approaches to player recruitment and development
which influences the success of UEFAs legislation around protecting opportunities for
young players in Europe.

*Home-grown legislation - consideration of programme theory?*

UEFA designed the home-grown rule as a response to changing migration patterns and
a concern over the ability to protect opportunities for locally trained players (UEFA,
2005). However, the structure (and power) in football between governing bodies and
clubs is complex. The relationship between UEFA and the clubs has been described as
a 'principal-agent relationship' (Schubert, 2014) with UEFA needing the clubs to
compete in their competitions. Therefore clubs are required to adhere to UEFAs
legislative interventions (e.g. FFP, home-grown quotas).

Use of programme theory in sport has focussed on major events or participation
interventions, rather than multi-national, multi-agency regulatory intervention such as
UEFAs home-grown rule. The home-grown regulation is not a legacy programme like
an Olympic Games as such. To achieve the desired impact (i.e. greater protection
leading to improved opportunities for young indigenous players) a major operational
and cultural shift across Europe is required. Clubs have traditionally had youth
academies and developed players, and this process would happen regardless of UEFAs
intervention. It can be questioned whether any additionality in the system stems from
investment (of time and effort) as a result of the legislation, or something that would have taken place anyway (Weed, 2014, p. 112)? Attributing additionality from the regulations is difficult without a theory of change which explicitly develops clear expected outcomes that can be traced.

Programme theory identifies the outcomes pursued, the processes required to achieve them and an assessment of whether the outcomes achieved were generated by the assumed processes (Rogers, 2008). The UEFA legislation had two clear aims. First was to improve the training of young players and their level of opportunity, and second, was to see an improvement in the competitive balance in Europe (Dalziel et al. 2013). The rule would also allow ‘markets’ to maintain a geographic character (Miettinen and Parrish, 2007). Criticism of previous UEFA interventions, for example Morrow (2013) on FFP and Bullough et al (2016) for home-grown legislation, demonstrates how it is possible for clubs to circumvent UEFAs regulations (i.e. the assumed process). This may point to an issue in their design, in particular around the principles of programme theory and understanding how inputs, activities and outputs lead to expected outcomes. A theory of change should outline how programme inputs (e.g., finances and support) will be allocated or used to generate the desired outputs and outcomes (Weed, 2014). Coalter (2011) also suggested this should be a framework for analysis rather than a method of delivery.

Previous work around the use of programme theory in sport (Coalter, 2007, 2011; Weed, 2014), noted three main concerns. First, there tends to be a focus on outputs not process and outcomes, second, the use of cross-sectional rather than time series data, third, a failure to factor and control dominant variables that are wide in range and
sometimes conflicting. It could be argued retrospectively that the construction and
imposition of UEFAs regulations appears to have a limited theory of change
underpinning it. The rationale could also be criticised for (1) focussing on outputs not
the process and (2) not controlling dominant variables.

The control of dominant variables is a clear weakness in the design of the home-grown
rule as the majority are not under UEFAs direct control. The UEFA quota rules are
imposed across the continent, although the inputs (and thus the influencing factors)
vary significantly between countries. Inputs, in a football context, include those at
both individual club level and national association/league level. For clubs, influences
on inputs can emanate through youth development philosophy and the approach to
player development, player trading strategy, ownership model and financial budget for
transfers and financial budget for the academy. At national association/league level,
influences include third party finance deals e.g. TV rights/sponsorship, European
competition allocation, league structure, coaching infrastructure and coaching volume.
This creates a complex environment and reduces the ability of key stakeholders to
control dominant variables, as outlined above. Issues can also arise when policy
makers become more concerned with demonstrating what the outcomes are ahead of
delivering them, particularly if interventions are the product of political decisions
requiring justification (Weiss, 1993; Weed 2014). In the case of the home-grown
legislation, the policy was designed due to a desire within UEFA to protect indigenous
players (Dalziel et al, 2013).

A significant amount of additional revenues have come into the game through UEFA
competitions and through commercial activity such as sponsorship and enhanced
media deals. However, an additional complication is that inputs in European football are not homogenous between leagues or between clubs in the same league. For example, between leagues, England have a more equal financial distribution model than Spain and Italy (Wilson et al, 2018); however the Premier League's bottom clubs receive more media revenue than the top clubs in other leagues, apart from Barcelona and Real Madrid in Spain who have historically received a higher allocation that the other La Liga clubs (Storm and Solberg, 2018). Many of the inputs influencing player development and recruitment are not, therefore, controlled by UEFA or directly under their jurisdiction. As the level of financial input is not standardised in terms of equal distribution (Wilson et al, 2018) or, importantly, not allocated specifically to the activities related to indigenous youth development. Clubs are free to formulate and execute their own strategy for resource allocation for recruitment, development etc. UEFA's ability to influence the necessary actions required to achieve the desire to increase opportunities, as set out in the rationale for the regulation, therefore, is weak.

It is an assumption to suggest that programme theory was not considered in UEFA's design of their home-grown regulations. Programme theory can be used retrospectively to illustrate the expected outcomes i.e. what was meant to happen (Figure 1) with what has actually happened (see results section). This is in-line with Coalter's (2011) suggestion that programme theory should be a framework for analysis rather than a method of delivery.

![Figure 1 'Assumed' Home grown rule logic model (UEFA) - here](image)

METHOD
This research had three main aims. First, examine the player production data from leagues and individual clubs in six European leagues (2006-07 to 2015-16). Second, analyse player development 'outputs' in relation to league structure (second teams). Third, discuss the design of UEFA's legislation in terms of programme theory; examining UEFA's expected outcomes against what has occurred.

The categorisation of clubs was chosen to follow the methodology and sample timeframe from Bullough and Jordan (2017) to allow a comparison across the six leagues. Clubs were categorised into four groups depending on their top-flight record in the ten year period, (1) ever-present, (2) majority (6-9) of seasons, (3) minority (2-5) of seasons, and (4) one season. A fifth group was not included in this study, but is worthy of note as part of the supply chain. It accounts for all other clubs with no seasons in the top league, but may still have a presence in terms of developing players which progress into the top leagues. The sample time frame was the first ten seasons of competition from the introduction of the home-grown regulations (2006-07 to 2015-16).

Previous studies in this area have outlined the different measurement techniques applied to assess playing opportunity, including starting eleven, squad composition, appearances made and minutes played (Gratton and Solberg, 2007; McGovern, 2002; Bullough and Mills 2014; Bullough et. al., 2016). In order to ensure the most accurate measurement of quantity and quality, the most recent studies have developed to analyse the volume of activity (namely minutes) as the most accurate descriptor of opportunity levels. This allows volume to be aggregated to demonstrate opportunity levels in a more comprehensive way than using the composition of teams/squads and
appearances. If players attended two different clubs' in their formative years (under 18), both clubs are credited with a role in that players' development.

Sample

The overall number of eligible teams in the sample (n = 200) from the six leagues can be split by nationality (Table 1) with England (37) having the most teams appearing in their top flight followed by France (36), Spain (35), Italy (34), Germany (33), and Holland (25). Germany and Holland have 18 team leagues; the other four nations have 20 teams per season. Italy has the lowest proportion of ever-present teams in this sample but has eight clubs with nine seasons in Serie A, three of which (Juventus, Napoli, and Genoa) were all promoted in 2006-07 and were then ever-present to 2016.

The variables collected for each player were: playing data (minutes and appearances), season(s) played, nationality, academy attended, team played for, and league played in.

The competitive nature of ten European leagues (including Portugal, Russia, Scotland and Switzerland) was assessed by Ramchandani (2012) with the French Ligue 1 the most competitive and the Eredivisie (Netherlands) the least (10th). The Eredivisie has the lowest diversity of clubs (25) and the lowest 'turnover' of clubs, with 10 being ever-present (matched only in France), and only two clubs playing one season (the other leagues average eight single season clubs). Despite this, Netherlands is included as they have been shown to be a prominent producer of young players, as outlined earlier.

Table 1 Sample of clubs - here
The number of eligible teams in the sample with a second team competing in the professional system varies between nations with England (0 out of 37) and Italy (0/34) not allowing this in their structure. The majority of clubs in the sample from Spain (33/35) and Germany (18/33) have this structure, with France (13/36) and Holland (9/25) having a minority of clubs with a second team. Overall 73 of the 200 clubs in the sample have a second team in the professional structure. This difference was investigated and forms part of the results section.

**Data Analysis**

To meet the three aims of the paper (to quantify outputs and investigate league structure in order to inform the discussion on the design of the legislation), playing data from each team in each season was collated and coded using SPSS. The following variables were collated; name, age, nationality, club played for, league played in, academy/academies attended, appearances, minutes played, and international caps (senior and age-group). This data was then categorised subject to key areas of interest (i.e. academy attended, team played for). To meet the aims of the paper, the descriptive statistics function allowed the calculation of whole system outputs (by national association). Subsequently, splitting the file into sub-groups (clubs, season, academy attended) enabled the volume of cumulative playing data, number of players etc. to be quantified. Playing data was then cross-checked to examine whether the academy attended and the club played for matched, in order to determine the rate of transition from academy to first-team in the same club. This methodology recognises where clubs give indigenous youth opportunities overall, although only aggregates data for eligible players i.e. those debuting since 2005-06. However, the data is robust and accurate quantification of the elite European football pathway, accounting
for 3,329 players, making 139,273 appearances, and generating 9,390,136 minutes of play.

RESULTS

The results section is structured into three areas, first in relation to the whole system, second individual clubs and club types (see Table 1), and third, league structure. For individual clubs, the analysis measured the overall production figures and academy players making the transition into their first team.

Whole system

Four of the six leagues comprise 20 teams (France, Germany, Italy and Spain with 200 elite league spaces across 10 years) and two comprise 18 teams (Germany and Holland with 180 league spaces).

For this sample i.e. the emergence of player's since the home-grown rule was imposed, the headline number of top-flight players produced in each system 2006-2016 include Spain (710), France (647), Holland (563), Italy (521), Germany (519), and England (369). The level of production varies considerably between countries with Spain (the highest) producing almost twice the amount of players than England (the lowest). The two 18-team leagues (Holland, 563, and Germany, 519) produced a similar amount of top-flight players; the greater range emanated from the 20-team leagues (+/-341).

On average, 339 indigenous players debut each season in one of the six main leagues (an average of 57 per league), although the top (Spain) average 71 new players and the bottom (England) register 37, with France (65), Holland (63), Germany (52) and Italy
An average of 325 players debuted in each of the first three years post-legislation (2005-08), and 370 in the last three years in the sample (2013-16). Against the expected outcome (Figure 1) that "legislation leads to a greater number of indigenous players recruited and retained by elite clubs", the outputs show a minor improvement. This marginal increase does not represent widespread culture change, more a case that France and Holland have seen some increases. Spain (71 new players per season on average) and Germany (51) have both remained consistent over the ten year sample. England have seen a small increase in the last three years compared to the first three (34 to 43) but are still lower than the other five nations; Italy have seen a decline in terms of the average number of debuting players (63 to 54).

Individual clubs

The outputs by individual clubs outlines that four of the top six clubs producing top-flight players reside in Spain, seven of the top 20 clubs play in the Dutch league, three French. In terms of playing opportunities for indigenous players since 2006 (regardless of their year of debut and academy development background) 18 clubs have facilitated over 200,000 minutes of playing time for indigenous players although there are notable exceptions. Athletic Bilbao has overseen 347,193 minutes by Spanish players, almost 85,000 minutes more than the next highest club (Feyenoord, 262,751). Only one German team (Bayer Leverkusen) are in the top 20 overall, and the highest English team (Aston Villa) are 37th (out of 200). One club (Arsenal) have recorded more minutes by French players (96,687) and Spanish players (52,102) than English players (40,154) from 2006-16. This includes all playing opportunities, not just those players making their debut since 2006.
The highest ranked clubs from Germany (#13), Italy (#15) and England (#18) are all outside the top 10; and England only has three clubs in the top 50. Interestingly, the two most successful Spanish clubs (Barcelona and Real Madrid) have a strong record of development in terms of players produced (68 and 58 respectively) and also representing that club (21 and 24). This volume of development is not necessarily replicated by the most successful clubs in the other leagues outside of Holland. Ajax (99) and Feyenoord (71) are the leading European clubs for player production in the sample timeframe. Table 2 outlines the leading clubs for players produced and minutes played (overall), and also for the clubs providing the most opportunity for their own academy graduates.

Table 2 Total produced - Overall and Same club (Category 1, unless stated) -

Four clubs stand out in the sample in terms of producing players; Ajax (99), Feyenoord (71), Barcelona (68), Real Madrid (58), Feyenoord (36), Utrecht (36), and Athletic Bilbao (32) saw the most indigenous academy players transition into their first-team. Feyenoord and Athletic Bilbao are the only two clubs to appear at the top of both lists for providing ‘same club’ opportunities. The Bilbao data can be identified as a direct result of their policy to only select players with Basque heritage, developed through their own club structure. At the opposite end of the production level, four category 1 clubs have produced ten or fewer players transitioning into one of the top 6 European leagues between 2006-2016; one Dutch (Heracles Almelo, 4 players), two English (Manchester City, 6; and Chelsea, 10) and one Italian (Udinese, 6). This demonstrates the varying approaches to player development and the provision of playing opportunities between clubs in Europe.
Overall, 19 clubs have produced five or more players since 2006 which have played at senior international level with Ajax (14) Feyenoord (13) and Barcelona (10) the only three clubs to reach double figures: 9 (Real Madrid) 7 (Bayern Munich, Schalke, Stuttgart) 6 (Atlético Madrid, Lyon, Manchester United, Valencia) 5 (AC Milan, Borussia Dortmund, Liverpool, PSV Eindhoven, Tottenham Hotspur, Juventus, Southampton, Sparta Rotterdam). One interesting example is Schalke 04, the club with the highest number of caps from academy graduates up to Euro 2016 (236 caps), with notable players such as Özil, Neuer, Höwedes, Draxler, Gündogan and Sané passing through the Schalke academy system during their developmental years.

Category 1 - Ever-present clubs

Category 1 is an important group as this is (generally) where the league winners and Champions League qualifiers reside (Italy apart, with Juventus in category 2), meaning players are playing in title chasing clubs and in the premier European competition. The 51 clubs in category 1 (i.e. ever-present) make up 25% of the sample, but account for over half (51%) of both the appearances made (70,903/139,273) and minutes played (4,757,264/9,390,136) between 2006 and 2016. However, these outputs differ by national association and by club in terms of both volume and averages. Dutch and Spanish category 1 clubs have played a role in developing a higher number of players (411 and 336) and average (41 for Dutch; 42 Spanish) per club. Compared to the other four nations, this is much higher than France (averaging 25 players per club), Germany (22), Italy (21) and England (18). In terms of the average number of players playing for the club in which they developed, for the
Category 1 clubs Netherlands (23) and Spain (20) have the highest followed by France (18), Germany (13), England and Italy (both 11).

For the volume of minutes played in the six leagues (Table 3), Dutch (1,482,339) and Spanish (1,008,967) players developing through category 1 clubs played a greater number of minutes than France (843,391) and Germany (752,289). This volume significantly decreases for England (373,873) and Italy (296,405). As each category has a different number of clubs, the averages provide additional context, and demonstrate that the eight ever-present Spanish clubs and the ten ever-present Dutch clubs have the greatest outputs per club. Dutch clubs in Category 1 average 148,234 minutes of activity for players they produced and an average of 50,485 minutes played at the club in which they developed, followed by an average of 126,121 minutes in Spain (averaging 36,931 minutes in their 'parent' club). The figures at the opposite end of the scale in Category 1 further demonstrate the disparity in England and Italy. English (total 46,734; average 11,808) and Italian (total 49,401; average 8,919) Category 1 clubs are behind the other nations in terms of player development opportunities. Italy have a higher volume in category 2 (the only nation where this occurs) due to three of their stronger clubs in the last ten years (Juventus, Genoa and Napoli) being in this category.

'Leakage'

The database outlines the presence of 'leakage' in the youth development system i.e. players going to other top flight clubs' academies which are outside of their national
association to develop, as discussed in the literature (Littlewood et al, 2011; Poli et al
2016; Bond, 2016; Richardson et al, 2012). Although this occurrence can be beneficial
to players and clubs, certain countries have been shown to be more popular
destinations and this additional line of supply can have an impact on the opportunities
available, with the home-grown rules being 'regardless of nationality'. The database
shows that 79 players in the sample have developed, at some stage, through the youth
system of a club in one of the six leagues outside their own national association,
although the contrast between nations is stark. Overall, 51 of the 79 players 'leaking'
from their system moved their development to England, predominantly through
category 1 clubs (40/51). With globalised ownership models prominent in England,
this somewhat reflects part of the culture in English clubs, where the best players, not
necessarily the best indigenous players, populate some academy teams. The financial
rewards on offer in England are also significant (Plumley et al, 2018) and often higher
than other leagues, which can be an influencing factor for players/agents.

Stockpiling of talented young players (for example, those with junior international
experience) also occurs at some clubs, with limited first-team opportunities on offer.
There are high profile clubs in the sample where their academy graduates have
generated a high number of international caps at junior level (up to Euro 2016) but had
not generated many first team minutes in the top-flight relative to the volume of junior
international experience. For example, Inter Milan, are credited with 29 academy
players but these 29 have a modest level of experience at senior international level (2
players, each with 21 caps up to Euro 2016); however at junior level, the same players
recorded 541 under 16-20 appearances and 201 appearances for the under 21s.
Chelsea's academy graduates had the highest number of under 21 caps for any English
club (95) but had only recorded 21,919 minutes of top-flight football, 1,085 of which for Chelsea. There is a danger that junior internationals are registered to some clubs where their first-team opportunities will be limited, if the culture and philosophy is weaker towards providing opportunities for players coming through the academy system.

League Structure

As discussed earlier, the presence of second teams in the league structure is not permitted in all leagues, and the player production data can isolate those clubs that have a second team (n = 73) and those that do not (n = 127). Those clubs with a second team in the sample have a greater average number of seasons in the top league (7) compared to those without (5). They have also produced a higher average number of players through their club (21 per club) compared to 12 for clubs with no second team. This difference is also present for the players emerging to play for the same club in the first team (an average of 12 players compared to 7). Players playing at the club they developed at also generate a greater volume of appearances and playing time, averaging 51 top-flight appearances each compared to 41 for other clubs, and 3,421 minutes each (versus 2,737).

For those clubs with a second team, there appears to be strength in this structure (i.e. develop players in the same environment to make the transition easier), see Table 4. A similar proportion of players transitioned into their parent clubs' first team at some point in their career for clubs with a second team (59%) and clubs without a second team (62%). There are, however, differences in volume for 'same club transition'. In total, 26,710 'same club' appearances were made at those clubs with a second team
compared to 20,335 for those without, generating 1,750,724 versus 1,342,495 minutes played respectively. This means that, with 53 fewer clubs, the sample of those with a second team produce a similar number of players, but generate a greater volume of overall playing time and developmental outputs via more a prominent level of transition into the first team.

The advantages of having a second team include involvement in the club environment/philosophy, access to similar facilities/coaches, potential for smoother transition, familiarity, support, not having to move etc. Although the removal of transfer fees applies to youth teams as well as second teams, critically youth teams do not play in the professional structure in the way B teams do. Culturally, this structure is not followed in England and Italy with a much wider breadth of professional clubs and there are no plans to change this structure.

Table 4 Outputs by 'second team in league' allowance - here

DISCUSSION

The purpose of the research was to examine European player development, with a focus on individual clubs and national associations, league structure and an application of programme theory. By widening the scope of nations, the results examine the impact of the legislation within clubs across six European leagues (Spain, Germany, France, Italy, Netherlands and England) over ten seasons between 2006-07 and 2015-16. This aims to identify the most prominent player development pathways in the main European leagues with regard to the clubs, type of clubs and the potential role of league structure.
The role of UEFA and individual national associations in the process of facilitating indigenous opportunities is reliant on the philosophy and actions of individual clubs/within leagues. The outputs generated outline that the 'direction of travel' over ten seasons is effectively a plateau in terms of volume. This has (as yet) not resulted in UEFA making amendments to the quota rules or tightening regulation (for example, ensuring nationality is a factor in the quota, rewarding clubs with high indigenous outputs). The outputs generated need to be rationalised around the process in which they operate, i.e. where UEFA as the governing body has a weak level of power to influence different behaviour by clubs to achieve the anticipated outcomes. The influence of nationality on organisational values and behaviours is an important factor (Hofstede, 1980), and 'clusters' of nationalities demonstrate differences in values, attitudes and goals (Ronen and Shenkar, 1985). Legislation, in the form UEFA introduced, does not account for differences between nations in terms of culture and behaviour within organisations around player recruitment and development.

The anticipated outcome of a greater number of young indigenous players being given opportunities has only seen a marginal positive benefit, with an average of 325 players debuting per season in the first three years post-legislation, and 370 in the last three years in the sample. The outputs suggest that there has not been a systematic culture change amongst clubs; therefore the anticipated outcome has not been achieved. UEFA's expected outcome of greater opportunity is yet to materialise on a macro level, although there is evidence of some protection of opportunity as there has not been a decline.
For a young player, it could be argued that the main supply 'should' be through your parent club, however in the modern game this is far from the case, with youth transfers and the role of agents for academy players becoming more prevalent. With scouting networks evolving and widening (Poli et al, 2016; Bond et al, 2016), making the grade as a professional has arguably never been more competitive. If opportunities for 'local' players are deemed worthy of protecting in the future, stronger regulation may be required to underpin any legislative developments. Some clubs/national associations stand out from the sample in terms of outputs, and there appears to be correlations between league outputs and league structures (i.e. second teams in the professional structure), although this is not suggested to be direct causation. The national association with the highest outputs (and also the greatest level of international success in the last decade) is Spain, where 33/35 clubs in the sample have a second team in the league structure.

For individual clubs, Athletic Bilbao is an outlier in terms of their approach, where over one hundred years of history is in place driving a philosophy of playing only those with Basque heritage. A club owned by its members embodies the local cultural identity under the idea that 'with home grown talent and local support, you do not need imports' (Vaczi, 2015). Ajax and Feyenoord also appear to have a philosophy of producing their own players which is reflected in the results, although without the direct cultural significance of Bilbao. Ajax had (up to 2015-16) only exceeded the £10m barrier for an incoming transfer once in the sample timeframe; Feyenoord had never done so. In context, the top 100 all-time transfer fees to July 2016 are all above £33m.
For national associations, although Spain leads the way, Germany has a more modest output level but with an 18 team league (which reduces the number of fixtures) appear to have a development system producing high quality. Germany has registered a World Cup win, two third places and two European semi-final appearances since 2006. Dutch clubs have a high volume (quantity) of players and playing opportunities, but in the least competitive of the major European league (Ramchandani, 2012). The Netherlands (alongside Italy and England), however, have all missed major tournaments since 2006.

Programme theory tested - expected outcomes or unintended consequences?

A programme theory approach allows us to assess the efficacy and legitimacy of implementing a 'strategy' and allows researchers to attribute outcomes to interventions (Weed, 2014). Tracing a path from the objectives and inputs to the outputs and outcomes stipulated "is an approach that is particularly appropriate when programmes have complicated (multiple streams) and/or complex (dynamic) elements" (Weed, p. 110).

Programme theory can, therefore, be used to illustrate what was meant to happen with the implementation of the regulations, with what actually happened. European football (leagues, clubs, financial models, ownership etc.) is not homogenous, operating in different environments with different financial resources. For UEFA to be able to identify and evaluate change (expected and unexpected), there is a need for them to understand how change occurs and what the causal mechanisms are. The control UEFA have over the player development process is limited beyond setting the legislation. As Coyle (2018) outlined, decisions taken by organisations reveal its
identity and bias, and test the preferences of leaders against reality. For clubs that
value commercial advantage and/or short-term transfers in the pursuit of trophies over
youth development, UEFA have limited influence on such organisational values.

Assessing the legislation against the principles outlined in Figure 1 outlines clear
deficiencies in the design. First, UEFAs legislation did not allocate any additional
'inputs' to clubs being affected by the quotas (namely financial resources) and this is a
key component to drive positive change and influence future behaviour. Second, the
process (i.e. the resource allocation and activities that create the outputs) are not
agreed or coordinated between clubs/leagues/national associations. Third, the
regulations are not strictly imposed (in that home-grown players do not have to be
indigenous to the country they play in, and the home-grown quota is a small minority
of the squad) which impacts on the outputs generated. Fourth, any change in behaviour
and approach is not explicit, nor consistent between clubs, and does not appear to have
changed significantly. Fifth, questions remain regarding the attribution of any change
to the regulation being introduced. Finally, the literature available, which highlights
increasing transfers of youth players and changing player migration patterns, may be
an unintended (potentially negative) consequence of the legislation.

A more rigorous underpinning theory of change (and level of influence) would be
required than was in place for the home-grown rule to have a greater impact, and
achieve the desired outcomes. For any new rule to demonstrate genuine, traceable
change, outlining what is expected through its implementation is important.
Understanding the efficacy of the legislation, and identifying any unexpected
outcomes should be considerations for future policy developments around protecting
indigenous/youth playing opportunities. Concentrating on outputs not process and not
being able to control dominant variables are issues for macro level interventions.
UEFAs ability to control the dominant variables is weak, and this is a prominent issue
in terms of its ability to influence the elite clubs and leagues. In addition, the cultural
differences between countries outlined earlier (Hofstede, 1980; Ronen and Shenkar,
1985) are potentially significant influences on behaviour within clubs. This is not in
UEFAs control, and appears to have not been a factor in the design.

The data demonstrates there has not been a major cultural or operational change in the
first 10 years, albeit with some protection with marginal increases in three countries,
and a minority of clubs with higher outputs (Table 2). The contradictions outlined
between the expected and actual outcomes are a demonstration of the difficulties in
exercising power in complex structures (Houlihan and Green, 2009). The significant
autonomy of clubs in Europe reduces the ability of UEFA as the governing body to set
a new strategic direction from a position of strength, allied with a limited level of
power to manage/change the behaviour within clubs.

Limitations
The methodology recognises where clubs have given indigenous youth opportunities,
however, not those debuting since 2005-06. It is arguably weaker when applied to
indigenous players that clubs have purchased, rather than developed through their
academy. A good example is Tottenham, generating 148,798 minutes played by
English players in the ten seasons, but 53,950 (36%) by players eligible to be included
in this sample. Tottenham's minutes have largely been generated by purchased players
(e.g. Ali, Trippier, Rose, Dier, Walker); only 16,639 minutes of this volume (31%)
was accumulated by their academy graduates, the 64th highest in the sample of 200 clubs and 33/51 in category 1. Whether this is this a problem, however, can be debated. The club appears to have a positive approach towards playing English players compared to other English clubs (ranked 4/37); yet this approach does not necessarily reflect evidence of a pathway from their academy to first-team.

A second limitation relates to players changing the nationality they represent which can influence outputs. Players can switch nationality at senior level from junior level as the rules have been relaxed. Examples of players representing their country of birth (at junior level or senior internationals in friendlies), then switching is becoming more prominent. With nationality not now being a constant variable, changes can affect the results when assessing the efficacy of such legislation.

CONCLUDING COMMENTS

The results highlight that there are clearly differing cultures, philosophies and approaches between clubs in the main six European leagues which influences player development and the provision of playing opportunities. The legislative intervention by UEFA aimed to (1) improve the training of young players, (2) protect their level of opportunity and (3) improve the competitive balance in Europe (Dalziel et al. 2013). However, retrospective application of programme theory i.e. comparing expected and actual outcomes, suggests that UEFA failed to achieve most of their intended outcomes in the first ten seasons. This is largely a result of not being able to control and influence the dominant variables in the complex environment in which elite football operates. Implications from this research for UEFA to consider when designing legislation in the future include (1) taking wider consideration of cultural
differences (2) understanding the dominant variables and, importantly, how they can be influenced (3) introducing stronger parameters which reduce the ability of clubs to circumvent their legislation.

By applying programme theory to the legislation, we address two key questions. First, whether the activities observed would have taken place without the intervention in question (in this case, the home-grown rule) and second, whether the activities observed would have taken place in the same format without the intervention. Player production and international transfers happened prior to UEFAs rule change, and the outputs have recorded limited (if any) change in behaviour. The nature of player development, transfers and recruitment strategies have also evolved substantially as the game generates greater financial resources. Market conditions in each league vary considerably and also vary between clubs in the same league, in particular the leading clubs chasing trophies. UEFAs (arguably) weak design, in not making nationality a factor and their inability to control other dominant variables, are both flaws in the legislation, and have had little discernible influence on the behaviour of clubs. The design of the home-grown rule could be described as weak in terms of its ability to influence positive change in its current format, and meeting the rationale cited for its introduction.
