Abstract

Background: Within dual route models of reading, words with regular spelling to sound correspondences can be read successfully using lexical or non-lexical reading processes. Research has indicated that which of these pathways is used is influenced by the other items that form the presentation context. We extend these findings using acronym stimuli as targets, presenting them in contexts designed to cue reading through grapheme phoneme conversion or letter naming.

Method: In experiment 1, undergraduate participants ($n = 30$) read aloud stimuli presented onscreen. Response times and accuracy for target acronyms ambiguous in their print to pronunciation conversion (e.g. HIV versus NASA) were compared between two contexts. In one condition the majority of items were unambiguous acronyms (e.g. BBC). In the second condition, the non-target items were regular words (e.g. CAT). Experiment 2 administered the same reading task to a single case of semantic dementia.

Results: A significant interaction between presentation context and acronym pronunciation was observed, such that responses were faster and more accurate to items that were pronounced in the same way as the majority of other stimuli in the list. Similar, though more dramatic, context effects were observed in a case of semantic dementia.

Conclusions: We argue that context effects are pervasive in reading research and that presentation context should be considered when interpreting future findings, particularly in cases of aphasia and dyslexia.

Introduction

Dual route models of reading (e.g. Coltheart, Curtis, Atkins & Haller, 1993; Coltheart, Rastle, Perry, Langdon & Ziegler, 2001) propose two methods for generating phonology for written stimuli. Non-word (and novel word) pronunciation is accommodated by a rule based system which assigns the most common phoneme for each grapheme in the stimulus and assembles them sequentially. Following these rules will allow for phonology to be generated for new words. Grapheme-phoneme correspondence principles will also produce the correct reading for the majority of English words (e.g. MINT, HINT or TINT which are termed *regular words*). Unfortunately, English contains a number of words which are exceptions to these rules (*irregular words* like PINT). Pronouncing these words requires a second route, the lexical route, which contains stored representations of all known words and allows the appropriate phonology to be retrieved. By definition the lexical route is unable to offer a pronunciation for any stimulus that has not yet been stored in the lexicon. The literature concerning the circumstances under which each route is emphasized, and the factors which affect the processing of a written stimulus by either route, is extensive (e.g. Baluch & Besner, 1991; Reynolds & Besner, 2005a; 2005b; 2008). These studies commonly look at the extent to which reading regular and familiar words is modulated by contexts populated by novel or irregular words. The current study seeks to extend such work by considering a class of items that have been somewhat overlooked – acronyms. In particular, this work seeks to determine whether acronyms behave like other words with respect to the influence of *context* and whether the pattern is similar for normal and impaired (acquired dyslexic) reading. We will first establish what we mean by “context effects in reading” by highlighting key relevant findings in the literature.

Several studies have shown that the reading system in healthy individuals is able to adjust which of the available reading routes is used in order that processing best suits the context in which items are read (Baluch & Besner, 1991; Reynolds & Besner, 2005a; 2005b; 2008; Zevin & Balota, 2000). Simply put, when the majority of the stimuli in a list require processing in a particular way (e.g. they are irregular, and can only be pronounced correctly using the lexical route) the reading system adjusts to focus on this route for the entire reading task. If a given item cannot be read using the emphasized route the switch between processes takes some additional effort, resulting in longer response times and a greater number of errors. Baluch and Besner (1991), for example, demonstrated the effect of list context using the Persian language. They found that the presence or absence of non-words in the reading list affected the processing of transparent words – those items that could, in principle, be successfully pronounced using either reading route. When the list did not contain non-words, high frequency transparent words were processed more quickly than their low frequency counterparts, indicating that participants were using the lexical route. When non-words were presented as part of the list of stimuli, responses to transparent words were not affected by frequency suggesting that they were processed using the non-lexical route. Further evidence of the flexibility of the reading system was reported in a series of studies by Reynolds and Besner (2005a; 2005b; 2008) using the alternating runs paradigm. In this paradigm, irregular words and non-words are presented in a predictable sequence – two irregular words followed by two non-words and so on. Irregular words are read more slowly when preceded by non-words than when they follow another irregular word (and vice versa). This is consistent with the fact that both types of items depend on different processing routes such that moving from one item to another has a resource switching cost. Reynolds and Besner (2008) showed that no such switch cost was incurred when reading regular

words, irrespective of whether they are preceded by irregular words or non-words as successful reading of regular words can be accomplished via lexical and non-lexical processes.

It seems, then, that the way in which words are read aloud is influenced by the context in which these words appear. However, much less is yet understood about the processing of acronyms (BBC, HIV, NASA) and other abbreviations, which proliferate in academic journals, newspapers and social media, with new terms being coined on a regular basis. They are constructed by selecting the initial letters of each word in a phrase. This process often results in acronyms which comprise unusual or illegal combinations of letters so that they often resemble non-words in their orthographic form, and as they are intended as a shortcut for lengthy, often highly specialized, terms they may often be novel to the reader. The majority of acronyms (though not all) are pronounced one letter at a time – a pronunciation that is quite different from the rest of the words in the English language. A large proportion of acronyms contain only consonants (e.g. BBC or DVD). We have previously referred to this type of acronym as *unambiguous* (Izura & Playfoot, 2012) because it is immediately clear from the orthography of these items that naming each letter in turn is the only sensible way of generating a pronunciation. There are also acronyms that contain both vowels and consonants (e.g. HIV or NASA) in combinations that are plausible in the English language. As such these are *ambiguous* in that it is not immediately obvious whether they should be pronounced letter by letter or otherwise (Izura & Playfoot, 2012). This ambiguity is reflected in the fact that in some cases such vowel bearing acronyms are pronounced letter by letter (an acronym *typical* pronunciation); in others the pronunciation is “word-like” and acronym *atypical*. There is nothing about the spelling of HIV that makes it obvious that the pronunciation should be one letter at a time, nor is there anything that indicates that NASA

1
2
3 should be pronounced as a two-syllable word. Although there is still relatively little published
4
5 research concerning acronym reading, it has often been assumed that this complex and unusual
6
7 relationship between print and pronunciation would require that reference is made to stored
8
9 representations of acronym phonology (e.g. Laszlo & Federmeier, 2007; 2008). Under this
10
11 circumstance, all acronyms would be read by the lexical route, irrespective of their spelling,
12
13 pronunciation, or the context in which they appeared.
14
15
16
17
18

20
21

22 However, while there is considerable evidence to suggest that familiar acronyms do have
23
24 phonological representations in the lexicon much as words do (Brysbaert et al., 2009; Slattery et
25
26 al, 2006) our recent work has indicated that these representations do not necessarily need to be
27
28 accessed for a correct pronunciation to be reached (Izura & Playfoot, 2012; Playfoot, Izura &
29
30 Tree, 2013). Instead, we have argued that acronym naming can be achieved through the
31
32 application of a single sub-lexical rule. Izura and Playfoot (2012) asked undergraduate
33
34 participants to read aloud a list of ambiguous and unambiguous acronyms. The overall accuracy
35
36 rate was high (98%). Accuracy for unambiguous acronyms was near ceiling for all participants
37
38 (99.5%). Importantly, at the end of the naming trials Izura and Playfoot (2012) asked their
39
40 participants to indicate which of the acronyms they had been familiar with before the study
41
42 commenced. The authors provided a breakdown of the accuracy for each type of acronym
43
44 depending on whether the participants had indicated that they knew the item. When the
45
46 acronyms were unfamiliar to the participants, the accuracy for unambiguous acronyms (e.g.
47
48 BBC) was 100%, and ambiguous typical acronyms (e.g. HIV) were pronounced correctly on
49
50 98% of occasions. The accuracy for previously unfamiliar ambiguous atypically pronounced
51
52 acronyms (e.g. NASA) was far lower at 42%. Thus participants were highly accurate when

reading acronyms named letter by letter even when they reported that they had never previously encountered a particular item – that is to say when such items were effectively nonwords (and had to be read non-lexically). Unfamiliar (or nonword like) ambiguous and atypical acronyms were read much more poorly, indicating the need for a lexical process (developed by familiarisation) for success. It is therefore clear that although lexical representations may be stored for all acronyms, those with a predictable letter by letter pronunciation may not require that these representations are accessed during reading. Further evidence for the existence of a sublexical rule for reading acronyms has been provided by the examination of acronym processing in acquired dyslexia. Playfoot et al. (2013) described JD, a patient with semantic dementia. An archetypal feature of semantic dementia is surface dyslexia (Hodges, Patterson, Oxbury & Funnell, 1992; Coltheart, Saunders & Tree, 2010) which describes a deficit in reading irregular words while regular word reading is preserved. Reading errors in such cases tend to be “regularizations” (Marshall & Newcombe, 1973) in which irregular words are pronounced as if they had regular spelling to sound correspondences. Dual route theories argue that surface dyslexia is the consequence of a damaged lexical reading route, which leads to an over-reliance on the grapheme-phoneme correspondence rules. JD showed the typical surface dyslexic pattern in word reading suggesting that her lexical route had become compromised. However, she was able to read unambiguous (DVD) and ambiguous typical (HIV) acronyms at near-ceiling accuracy. It seems unlikely that a deficit in the lexical route would preserve representations for acronyms when words of a similar frequency had been lost. Thus, Playfoot et al (2013) argued that JD's successful reading of typical acronyms was underpinned by a rule based mechanism, either as a separate reading route or as integrated somehow in the grapheme – phoneme conversion route. These are important findings, because they indicate that some acronyms at

1
2
3 least (particularly those pronounced a letter at a time) could be successfully read using two
4
5 different processes. Our work with JD has provided evidence of a non-lexical method for
6
7 reading acronyms, which is presumably available to normal readers as well. Normal readers are
8
9 also likely to have access to stored representations of acronym pronunciations. We consider that
10
11 whether it is the lexical representation or the non-lexical rule that generates acronym
12
13 pronunciation in readers with an intact reading system may be contingent on the context in which
14
15 the acronym appears.
16
17
18
19

20
21
22
23
24 Interestingly, some evidence of context effects with acronyms was observed in the data reported
25
26 in both Izura and Playfoot (2012) and Playfoot et al. (2013). Izura and Playfoot (2012) reported
27
28 that, presented with a list containing only acronyms, undergraduate participants named
29
30 ambiguous atypical acronyms (e.g. NASA) significantly slower than ambiguous typical
31
32 acronyms (e.g., HIV). The authors suggested that the fact that the vast majority of the items to
33
34 be read required a letter by letter pronunciation meant that participants found it particularly
35
36 difficult to respond when they encountered a stimulus which needed an alternative spelling to
37
38 sound conversion. Playfoot et al., (2013) also found context effects in JD, a surface dyslexia
39
40 patient. For example, when she was presented with a mixed list containing both words and
41
42 acronyms, JD pronounced the vast majority of the items one letter at a time, irrespective of their
43
44 type. The same pattern was not observed when words and acronyms were presented in two
45
46 separate lists. Items in an acronym-only list were still predominantly pronounced a letter at a
47
48 time (JD was only inaccurate with ambiguous atypical acronyms like NASA). However, the
49
50 responses in the word-only list predominantly followed GPC rules, which is in line with the
51
52 pattern of regularization errors commonly reported in surface dyslexia (Marshall & Newcombe,
53
54
55
56
57
58
59
60

1973). JD’s reading system, therefore, seems sensitive to the characteristics of the items in the list, but is not sufficiently flexible to change strategy on a trial by trial basis (as is suggested by the research with normal participants) – rather a particular type of response bias is formed by context and remains throughout.

Although the above findings suggest an influence of presentation context on acronym reading, our previous work did not deliberately manipulate this potential factor. In this paper we present data from two experiments which intended to assess context effects explicitly. The stimuli of interest were ambiguous acronyms: both those with a typical pronunciation (HIV) and those with an atypical (NASA) pronunciation. These ambiguous acronyms were presented in lists which comprised a large proportion of unambiguous acronyms (BBC) or regular words (CAT). We have argued earlier that typical acronyms are pronounced in the same way, irrespective of whether they are ambiguous such as HIV or unambiguous such as BBC; ambiguous atypical acronyms follow the grapheme-phoneme correspondences which apply to mainstream words. Here, we manipulated the context in which ambiguous acronyms were read by preceding them with either unambiguous acronyms or regular words. Following the work of Baluch and Besner (1999) and Reynolds and Besner (2005; 2008), presenting a large proportion of similarly pronounced items will cue the use of a particular reading strategy. A list of unambiguous (BBC) acronyms will trigger a preference for letter by letter reading; a list predominantly made up of regular words may cue a lexical reading strategy (assuming that the lexical route is intact and viable). Emphasising one of these routes would make responses easier to generate for individual acronyms that followed the same print to pronunciation pattern as the surrounding context. Switch costs would be incurred for any item that requires an alternative process, and this could

1
2
3 be manifested in RT, accuracy or both. Specifically, letter by letter acronyms ought to elicit
4
5 faster responses and greater accuracy than atypical acronyms in a context where letter by letter
6
7 reading is encouraged. No significant difference between acronym types would be predicted if
8
9 all items were read via the lexical route (i.e. in the context of regular words).
10
11

12
13
14
15
16
17 In Experiment 1, we collected data from undergraduate participants in an attempt to determine a)
18
19 whether the difference in RT between ambiguous atypical (NASA) and ambiguous typical
20
21 acronyms (HIV) reported by Izura and Playfoot (2012) was a consequence of presenting a list of
22
23 stimuli predominantly requiring a letter by letter pronunciation and b) whether a similar context
24
25 effect would be observed in reading errors. Experiment 2 presented the same task to JD. The
26
27 rationale for this manipulation is the same as for Experiment 1. However, the nature of JD's
28
29 dementia is such that lexical reading may be precluded. In this case, the presentation of a set of
30
31 regular words is expected to cue the non-lexical GPC rules which apply to words. Practically
32
33 speaking, applying word GPC rules will result in the correct pronunciation of ambiguous atypical
34
35 acronyms and the incorrect pronunciation of typical letter by letter acronyms. Our previous
36
37 work indicated that JD had considerable problems in reading ambiguous atypical acronyms
38
39 whether they were presented with words in mixed lists or in pure blocks of acronyms (Playfoot et
40
41 al., 2013). If, as we suspect, this was the result of inflexibility in her reading system which
42
43 prevented her from breaking away from letter naming, then her inaccuracy should be limited to
44
45 circumstances in which letter naming is strongly cued by the presentation context. It is possible
46
47 to suggest, on the basis of the above findings, that JD might be more successful in reading
48
49 atypical acronyms (such as NASA) if they were embedded in a list of words. As most
50
51 ambiguous atypical acronyms are pronounced following GPC rules, reading accuracy ought to be
52
53
54
55
56
57
58
59
60

improved by including ambiguous atypical acronyms in blocks of regular words. The opposite effect should be observed in ambiguous typical acronyms like HIV. We would also argue that by emphasising GPC rules through the presentation of a list which is predominantly regular words, it is likely we will see an increase of instances of ambiguous typical acronyms being read as whole words. By contrast, cueing a letter by letter naming strategy ought to result in accurate ambiguous typical acronym reading.

Experiment 1 – healthy readers

Participants

Thirty native English speakers with a mean age of 20 (range 18 – 26) were recruited as participants in this study. The 3 male and 27 female participants were undergraduate psychology students at Swansea University. None of the participants had been diagnosed as dyslexic or suffered from other reading deficits, and all had normal or corrected-to-normal vision. Participants were given course credit for their participation in this experiment.

Materials and design

Twenty ambiguous acronyms were selected from Izura and Playfoot (2012). Ambiguous acronyms were presented in two contexts. One context consisted of 80 regular words. The second context comprised 80 unambiguous acronyms. Both contexts were presented alongside the ambiguous acronyms. Ambiguous acronyms are formed by vowels and consonants such that a mainstream word-like pronunciation is possible (HIV, NATO). Ten of the ambiguous acronyms chosen for this study were pronounced by naming each letter in turn (HIV, typical pronunciation for acronyms). The remaining 10 ambiguous acronyms (NATO) were pronounced according to grapheme to phoneme correspondences (atypically pronounced acronyms). The ambiguous typical (HIV) and ambiguous atypical (NATO) acronym sets were matched for printed frequency, rated frequency, summed bigram frequency, and age of acquisition as determined by non-significant t-tests (all $p > .1$). Values for these variables were taken from Izura and Playfoot (2012). Participants read aloud the ambiguous acronyms in both contexts. The order of presentation of the reading contexts was counterbalanced across participants. The regular word context contained eighty mainstream words selected from the CELEX database (Baayen et al., 1993). Mainstream words were regular according to the grapheme to phoneme correspondence rules of the DRC model of reading (Coltheart et al., 2001). Regular words contained between 3 and 5 letters (mean = 3.24). The second context used 80 unambiguous acronyms three or four letter (mean = 3.49), drawn from Izura and Playfoot (2012). Unambiguous acronyms are always pronounced in an acronym-typical manner (i.e. naming the letters). Unambiguous acronyms did not differ from the regular words in terms of length [$t < 1$], or printed frequency [$t < 1$]. Frequency values for the acronyms were taken from Izura and Playfoot (2012); regular word frequency from CELEX (Baayen et al., 1993). The stimuli used can be seen in appendix 1.

Procedure

Stimuli were presented in black colour Times New Roman font (size 12 points) on a white background. All stimuli were presented in upper case letters. Trial randomisation and stimulus presentation was controlled using E-Prime software (Schneider, Eschman, & Zuccolotto, 2002). Participants were instructed to read aloud the stimuli as they would do under any other circumstance, such as reading aloud from a magazine article, and that they should do this as quickly and accurately as possible. Once they had understood the instructions, the experiment began by pressing the space bar. Responses were detected by a microphone placed about 10 cm from the mouth. The time that had elapsed between the appearance of the stimulus and the first audible response was automatically recorded by the experiment software. The detection of a response initiated the presentation of a fixation cross which remained onscreen for 1500ms. This was replaced by the next target for reading. The session was audio recorded to allow for the offline analysis and removal of errors. Participants were given 5 practice trials (mainstream words irrespective of which condition the participant had first (i.e., acronym or regular word context)) at the start of the experiment to familiarize them with the procedure and avoid practice effects. The order of presentation of the two lists was counterbalanced across participants.

Results

1
2
3 Reading errors (2.2%) and voice key malfunctions (4.3%) were removed prior to analysis of the
4
5 reaction times. Following this, the mean and standard deviation for response latencies were
6
7 calculated for each participant. Response times more than 3 standard deviations above the mean
8
9 or prior to 300ms were designated as outliers and deleted. This process removed a further 1.7%
10
11 of all responses. Overall accuracy was high, but two participants were deleted from the analyses
12
13 because of very low (< 75%) accuracy in reading ambiguous atypical acronyms in the
14
15 unambiguous acronym context. Therefore the analyses reported here were performed on the data
16
17
18
19
20 from 28 participants.
21
22
23
24
25

26 Reaction time data was entered into two ANOVAs (2x2). Table 1 shows the mean reaction
27
28 times and accuracy rates for ambiguous typical and ambiguous atypical acronyms when
29
30 presented in the context of regular words or unambiguous acronyms.

41
42
43

44 Pronunciation typicality and reading context were submitted as within-subjects factor in the
45
46 analysis by subjects. In the by-items analysis, pronunciation typicality was considered a
47
48 between-subjects factor and context was treated as within-subjects. The overall main effect of
49
50 context was significant [$F(1, 27) = 41.916$, $MSe = 7791.186$, $p < .001$, $\eta^2 = .608$; $F(1, 18) =$
51
52 38.674 , $MSe = 2793.768$, $p < .001$, $\eta^2 = .682$] by subjects and by items. Responses were
53
54
55 significantly faster in the regular word context than in the acronym context. The main effect of
56
57
58
59
60

acronym pronunciation typicality [$F_1(1, 27) = 4.242$, $MSe = 4369.931$, $p < .05$, $\eta^2 = .136$] was significant in the analysis by subjects, but not by items [$F_2(1, 18) = 2.525$, $MSe = 5065.086$, $p > .1$]. The interaction between acronym pronunciation typicality and context was significant by subjects [$F_1(1, 27) = 21.043$, $MSe = 3124.558$, $p < .001$, $\eta^2 = .438$] and approached significance by items [$F_2(1, 18) = 3.882$, $MSe = 2793.768$, $p = .064$]. Post hoc t-test analyses (Bonferroni correction applied at $\alpha/2 = .025$) indicated that naming times for ambiguous atypical and ambiguous typical acronyms were not significantly different when surrounded by regular words ($t(27) = 1.85$, $p > .1$). However, when the reading context consisted of unambiguous acronyms, ambiguous atypical acronyms had significantly longer response latencies than ambiguous typical acronyms ($t(27) = 3.784$, $p < .005$). The interaction is presented in Figure 1 below.

[Figure 1 about here]

Accuracy rates were arcsine transformed prior to ANOVA analysis. Two ANOVAs (2x2) were performed. Pronunciation typicality and context were treated as within-subjects factors in the analysis by subjects; pronunciation typicality was considered a between-subjects factor in the analysis by items while context was a within-subjects variable. The main effect of context was not significant by subjects [$F_1(1, 27) = 2.808$, $MSe = 5.284$, $p > .1$] but was by items [$F_2(1, 18) = 6.291$, $MSe = 8.095$, $p < .05$, $\eta^2 = .259$]. The main effect of pronunciation typicality was not significant by subjects or by items. A significant interaction between pronunciation typicality and context was observed in both the by subjects and by items analyses [$F_1(1, 27) = 8.411$, $MSe = 6.988$, $p < .01$, $\eta^2 = .238$; $F_2(1, 18) = 9.047$, $MSe = 8.095$, $p < .01$, $\eta^2 = .334$]. Responses to

1
2
3 ambiguous atypical acronyms were more accurate when presented in the context of regular
4 words while ambiguous typical acronyms were pronounced with greater accuracy in the
5 unambiguous acronym context. Bonferroni corrected post hoc tests revealed that this interaction
6 was driven by significantly lower accuracy for typical acronyms in the word context than in the
7 acronym context ($t(27) = 3.400, p < .005$). This interaction is depicted in Figure 2.

26 Discussion 27 28 29 30 31

32 A significant interaction between pronunciation typicality and presentation was observed in the
33 reaction time data. In the unambiguous acronym context, ambiguous typical acronyms like HIV
34 were named significantly faster than ambiguous atypical acronyms, mirroring the findings of
35 Izura and Playfoot (2012). The difference between mean RT in this context was 75ms
36 (compared to 71ms in Izura & Playfoot, 2012) suggesting that there were indeed contextual
37 influences in our previous work. We suggest that this is likely the result of the switch cost
38 incurred in changing from an "acronym reading" to a "word reading" routine. In the regular
39 word context, on the other hand, no significant difference in RT between typical and atypical
40 acronyms was observed. Taking into account the significant main effect of context on naming
41 times reported here, with responses being faster overall in the regular word context, we argue
42 that all the items in this list were read using the faster lexical route. A pronunciation typicality by

presentation context interaction was also observed in the error data, with greater accuracy for typical acronyms in the acronym context than when presented alongside a large proportion of regular words. **Baluch and Besner (1991) indicated that the GPC route could be used to support reading of lists of items with lexical representations if the task was designed such that non-lexical conversion was a viable option. It is possible that the GPC route was used to support or inform acronym reading here in a similar way, and that errors in ambiguous typical acronym trials reflect that the switch from GPC to letter naming rules was unsuccessful. However, our RT data suggest that all items in the regular word context were read via the lexical route, so finding lower accuracy in this condition is puzzling.**

Experiment 2 – Semantic Dementia

Patient JD

JD’s semantic dementia profile has been described extensively elsewhere (Playfoot et al., 2013) so only a brief summary of the key information is included here. At the time of testing, JD was 62 years old. She is female and right-handed, had a university education and had been working as a legal secretary prior to her diagnosis. Her semantic system is considerably impaired, and hence she scores poorly in tests of semantic judgments (e.g. Pyramids and Palm-Trees, Howard & Patterson, 1992) and picture naming (Psycholinguistic Assessment of Language Processing in Aphasia, PALPA; Kay, Lesser & Coltheart, 1992). Her phonological skills are within the normal

range in word and non-word repetition (PALPA; Kay et al., 1992). JD is accurate in reading aloud regular words, but inaccurate with irregular words (Castles & Coltheart, 1993) thus exhibiting the typical surface dyslexic reading pattern (see Table 2, below). To reiterate, it was predicted that JD would be more successful in reading acronyms which followed the print to pronunciation pattern of the majority of the items in the list (i.e. greater accuracy for typical acronyms in the context of unambiguous acronyms; greater accuracy for atypical acronyms when presented alongside regular words).

[Table 2 about here]

Materials and procedure

Experiment 2 used the same stimuli as in experiment 1. The trials proceeded exactly as above. JD performed the word context first, followed by a 10 minute break and then the unambiguous context.

Results and discussion

JD's reading accuracy is presented in Table 3. Overall accuracy for ambiguous typical acronyms was greater than for ambiguous atypical acronyms. The proportion of correct responses in each presentation context is exactly the same. Chi-square was used to assess whether reading

accuracy for ambiguous atypical acronyms (NASA) was significantly lower than for ambiguous typical acronyms (HIV). It was determined that this difference was significant [$\chi^2(1) = 16.162$, $p < .001$]. As predicted, there was a significant effect of presentation context on accuracy in naming ambiguous acronyms. In the word context JD named a significantly greater number of atypical acronyms than typical acronyms [$\chi^2(1) = 98.990$, $p < .001$]. As JD named all of the typically pronounced acronyms correctly in the acronym context, formal analysis was not possible due to a cell count of zero at which point chi square analysis becomes inappropriate.

[Table 3 about here]

Despite the fact that there was no overall difference in the number of errors that JD made in each of the lists, a large context effect was apparent in her responses. Accuracy increased by 70% when the ambiguous acronyms were pronounced using the same process as the context items (i.e. regular words). As predicted, JD's reading system appears to be sensitive to the characteristics of the items presented to her such that strategy used to read the list is adjusted. The remarkably low accuracy for items which do not follow the same pattern as the remainder of the stimuli suggests that once this routine is set it is difficult for her to subsequently adjust. The pattern of errors observed in experiment 2 is similar to that observed in normal readers. However, in JD the deficit for items with unexpected pronunciations was much more severe.

General Discussion

In this paper we have demonstrated that a) presentation context can alter the way in which acronyms are read aloud, b) the normal reading system is flexible enough to accommodate switches between letter by letter and grapheme-phoneme correspondence pronunciation strategies and c) there is a considerable loss of flexibility when the reading system becomes damaged as it does in surface dyslexia. These findings illustrate the importance of context effects in reading, via the utilization of a largely under-used stimulus set – acronyms – and as such complement work with words. In both JD and, to a lesser extent, in healthy participants, acronym reading accuracy was significantly better when the ambiguous acronym (e.g. HIV or NASA) was pronounced in the same way as the majority of the items in the list of stimuli. The reading system seems sensitive to the characteristics of the items in the list, but in JD it is not sufficiently flexible to change strategy on a trial by trial basis. The result of this is that, once set to a particular strategy, JD names the vast majority of the stimuli in that way and is highly inaccurate when other pronunciations are required.

An alternative explanation may account for the pattern of performance we observed in JD in the current study. Simply, it is possible that the damage to JD's lexical reading mechanisms meant that she failed to recognise the acronyms, and hence that she merely pronounced them in line with print to pronunciation conversion she used for other items. That is to say, if she was not able to access a lexical representation for HIV when presented in the word context she may be inclined to use the same grapheme to phoneme correspondences she used for the words that she

1
2
3 did not recognise in the list. While this account would allow for the pattern of responses
4
5 observed in this study, it is not easily reconciled with our previous findings that JD's reading of
6
7 words was influenced by the presence of letter-by-letter acronyms (Playfoot et al., 2013).
8
9 Specifically we showed that she made frequent letter-by-letter reading errors in pronouncing
10
11 written words when the context included acronyms. As JD's lexical route is impaired, she relies
12
13 upon GPC rules to name words. However, the letter by letter processing strategy applied to
14
15 acronyms seems to override the GPC rules when words and acronyms are intermixed in the
16
17 reading task. The assumption that JD's errors in atypical acronym reading are based on a failure
18
19 to recognise them would therefore also have to apply to word reading errors. This seems
20
21 unlikely given that a) JD made fewer errors in word reading when no acronyms were presented
22
23 and b) the types of word reading errors that were made differed across contexts (Playfoot et al.,
24
25 2013).
26
27
28
29
30
31
32
33
34
35

36 In a few aspects, the pattern of performance in normal readers differed from that of JD. For
37
38 example, the inclusion of a regular word context created an advantage for ambiguous atypical
39
40 acronyms in JD by emphasising the grapheme to phoneme conversion system. In normal readers
41
42 no significant differences were observed in the naming rates for ambiguous typical (HIV) and
43
44 ambiguous atypical (NATO) acronyms, suggesting that the lexical route was used for all
45
46 ambiguous acronyms. This pattern mirrors those relating to transparent words that were reported
47
48 by Baluch and Besner (1991). Transparent words (i.e. those with obvious spelling to sound
49
50 mappings) were processed using the sublexical route when presented alongside non-words but
51
52 were read lexically when non-words were omitted. The findings we have presented here indicate
53
54 that items that are ambiguous in some way (in that they can be processed in more than one way
55
56
57
58
59
60

1
2
3 to arrive at the same pronunciation) can be affected by the context in which they are presented.
4
5 If context effects are indeed so pervasive in the reading of all kinds of different letter strings, it is
6
7 important that reading researchers undertaking work with normal or abnormal population pay
8
9 heed to such effects – as the consequences can have important implications in interpreting
10
11 performance (e.g., surface dyslexic severity may be reduced or amplified depending on stimulus
12
13 testing procedure).
14
15
16
17
18
19
20

21
22 The precise processes that underpin acronym reading have yet to be considered in the framework
23
24 of influential models of word reading. This may be due, in part, to the fact that relatively little
25
26 evidence regarding the reading of acronyms to inform such a theory had previously been
27
28 available. We contend that sufficient data has now been gathered (both from healthy readers and
29
30 acquired dyslexia) to allow for a dynamic theory of acronym reading to be proposed and
31
32 thoroughly tested. The data we have gathered here seems easily reconciled with a dual route type
33
34 of theory. In JD we have demonstrated that there may be a mechanism for pronouncing
35
36 acronyms a letter at a time which does not require access to lexical representations. It appears
37
38 that these letter naming rules exist in addition to the normal GPC rules that apply to regular
39
40 words, though whether it is an entirely separate route or a modification of the non-lexical route
41
42 proposed in DRC (Coltheart et al., 2001) remains an open question. The data gathered from
43
44 normal readers, in our own work and that which has been reported by others (Brysbaert et al.,
45
46 2009; Izura & Playfoot, 2012) indicates that acronyms have stored lexical representations. In the
47
48 present study we have demonstrated that while all acronyms can be read via a lexical route,
49
50 lexical reading is particularly necessary for ambiguous atypical acronyms such as NASA.
51
52 Importantly, our data indicate that all acronyms may be read via more than one processing route

(one lexical and one non-lexical) and that which mechanism is employed when an acronym is encountered is highly contingent on the reading context. The choice of reading strategy may be further constrained by damage to the reading system, as in the case of JD, which precludes the use of one of the available routes from print to pronunciation.
