Analyzing the impact of environmental collaboration among supply chain stakeholders on a firm's sustainable performance

Abstract- In the era of industrialization, environmentalists are more concerned with the environment and so are continuously interested in investigating organizational factors that can facilitate the transition towards sustainability. This research systematically investigates the impact of supply chain partner's collaborative approach towards green practices on a firm's sustainability performance. Stakeholder and coordination theories are used to underpin the study. A structural equation modeling technique is adopted to analyze data collected from 126 green supply chain professionals working at various manufacturing firms operating in Pakistan using a survey questionnaire. The results indicate significant and positive impacts of institution pressure and customer monitoring on the adoption of green supply chain management (GSCM) practices by organizations. This study also explains that organizational GSCM practices, external GSCM practices and performance measures have positive and significant relationships. These findings reveal that it is important for managers to address external GSCM pressures by adopting green practices and being a focal firm should undertake GSCM initiatives in collaboration with their suppliers and customers to achieve a holistic impact which ultimately leads to betterment in overall sustainability performance.

Keywords: *Green supply chain; Stakeholder theory; Coordination theory; Supplier collaboration; Customer collaboration; Environmental performance, Organizational performance*

1. Introduction

Businesses exist to offer solutions, grow and make a profit. However, in the quest of offering these solutions which lead to their growth and profitability, they tend to neglect the environmental impact their operations create and the economic implications that come along (Kusi-Sarpong et al, 2015, Kusi-Sarpong et al., 2018; Khan et al., 2018; Zhu and Sarkis, 2004). The environmental impact of business operations has received less attention until the 1990s where supply chain operations started considering the effects of business operations on the environment (Sarkis et al., 1999). One of the major considerations was the concept of green supply chain management (Kusi-Sarpong et al., 2016; Sarkis, 1999; Sarkis and Weinrach, 2001; Sarkis and Cordeiro, 2001). Green supply chain considers the impact on the environment with regards to sourcing of raw materials, product composition, manufacturing and delivery to the final consumer as well as product life cycle (Bajaj et al., 2016; Bai et al., 2017; Beamon, 1999; Kusi-Sarpong et al., 2016; Sarkis, 2003).

Organizations react to environmental pressures exerted by different stakeholders based on their distinct norms, rules or institutions, conventionally manufacturers bear the regulatory pressures from government and due to these regulatory pressures they adopted reactive internal green supply chain management practices (Zhu et al., 2016). Institutional pressure is an important driver and positively affects the adoption of green supply chain management practices in organizations (Yang, 2017). Due to stern regulations and likely competitive benefits, manufacturers have adopted assorted green practices (Govindan et al., 2014; Mathiyazhagan et al., 2014). Furthermore, institutional pressures influence organizations to pursue green supply chain management practices (Vanalle et al., 2017). Institutional theory has been used to explain the adoption of environmental management initiatives and green supply chain practices by organizations (Zhu et al., 2013). Stakeholders such as customers, suppliers, and competitors may wield pressure on manufacturers to adopt environmental management practices due to increased public awareness and ongoing damage to the environment (Zhu et al., 2012).

Previous literature highlights the fact that environmental pressure from stakeholders has increased considerable attention due to the awareness of customers (Jabbour et al., 2017). Stakeholder theory has an important role to play in implementing green supply chain initiatives as a result of customer pressures (Chavez et al., 2016). External pressures play a compelling role in

the adoption of internal green supply chain initiatives (Abedanjo et al., 2016). Awareness of environmental fallout of manufacturing and production processes become a global phenomenon and it does not only exert pressure on organizations in developed economies but also firms operating in emerging economies in Asia (Geng et al., 2016). Pressures exerted by different stakeholders become the motivating factor for companies to implement environmentally friendly practices (Zhang & Yang, 2016). There is a need to emphasize beyond internal boundaries on external players in the supply chain to respond to growing environmental apprehensions of various stakeholders (Laari et al., 2016).

Organizations could get involved directly or indirectly to enhance the environmental practices of supply chain members either by using arm length approach or by investing in resources and internalizing the activities in supply chains (Vachon and Klassen, 2006). To use a holistic and integrative approach, organizations first have to adhere to environmental concerns as a strategic course of direction. This then leads it to design such processes, products, and environment-friendly services and then to propagate this approach to all levels of the organization and among supply chain partners (Green et al., 2012). Dimensions of internal green supply chain management include the upstream and downstream green supply chain. These have to be linked with an external green supply chain to include both customers and suppliers (Yu et al., 2014).

Organizations are now accepting environmental management as a strategic imperative with the prospect of indelible impact on organizational performance (Diabat and Govindan 2011). Internal green supply chain practices and external green collaborations help organizations to achieve green performance (Yang, 2017). Practicing of the green supply chain leads to benefits like a reduced waste, reduced hazardous air emissions, increased energy efficacy, reduced fuel consumption and less water wastage (Bajaj, et al., 2016).

Previous studies have shown inconclusive results which states that there is no significant effect of green practices found on financial performance (Zhang and Yang, 2016), mixed results were reported for effect of external and internal green practices on environmental, financial and operational performance (Zailani et al., 2012; Lee et al., 2012; Lai and Wong, 2015; Green et al, 2012a; Ahmed et al., 2018; Vachon and Klassen, 2008; Jayaraman et al., 2016; Golicic and Smith, 2013) and no support was found for green supply chain practices on operational performance (Vanalle et al., 2017; Zhu et al. 2007). These mixed results warrant additional detailed holistic

investigation to further clarify these relationships between green practices and performance measures (Geng et al., 2016). This study focuses on the Pakistan manufacturing industry to investigate this relationship to help contribute to the closing up of this literature gap and confusion.

This study targets Pakistan and its manufacturing industry due to its recent and potential growth. Pakistan is seen as an expeditiously developing country and as one of the next eleven countries along with BRICS that has high potential to stand with the world's largest economies in the 21st century (www.kcci.com.pk). On a worldwide scale, Pakistan's enormous economic potential has been acknowledged as per the Price Water House Coopers report of 2017. Pakistan is envisaged to become the world's 20th largest economy by 2030 and will become the 16th largest economy of the world by 2050 (Hussain, 2017). There are several prestigious and reputable international publishers like Bloomberg and Economist etc. which have also acknowledged Pakistan's impressive economic growth over the last four years (www.finance.gov.pk). The manufacturing sector in Pakistan is the backbone of the economy and it is the second-largest segment of the economy making 13.5% of GDP. Additionally, the manufacturing sector is the largest employment generator in the economy of Pakistan. The manufacturing sector further subdivided into large scale manufacturing which is 80% of the total sector and 10.7 % of GDP whereas small scale manufacturing sector is 13.7% of the total manufacturing sector and constitutes 1.8% to GDP. Overall, the manufacturing sector has had study growth. There was an impressive growth of 5.3% in the 2017 financial year as against 3.7% in the previous year (www.finance.gov.pk). This study draws empirical information from the large scale Pakistan manufacturing companies as studies have shown that the size of organizations affects their environmental performance (see e.g. Pagell et al., 2004). Pakistan is the fifth most densely populated country in the world having its impact on pollution index. Pakistan manufacturing companies though are flourishing but lack the necessary direction and support for gaining much more insight to drive and improve environmental performance. This is mainly due to a trust deficit, unwillingness to invest in environmental management and mostly due to ignorance among the partners. Pakistan's context of this study will enrich the literature, as this will be the first study in a holistic and integrated manner to examine the external pressures for adopting green supply chain practices and its relationship with various performance measures directly and indirectly. The objective of this paper is as follows:

1. To develop a framework to understand the motivation and pressures behind GSCM implementation.
2. To understand the effect of collaborations of different stake-holders to improve operational and financial performance.
3. To explore the factors which contribute to improving the environmental performance of a firm.

Theses objective posits following research questions

RQ1 - What are the driving forces of implementing GSCM in an organization?

RQ2 - What are the interconnections among the key stakeholder to get better operational and financial performance?

RQ3 - What are the impact of GSCM and collaborative practices on the environmental performance of the firm?

The rest of the paper is organized in the following manner. Section 2 discusses the theoretical background underpinning the study and hypotheses, and the methodology adopted in the study is presented in Section 3. Results and Data analysis presented in Section 4, and the conclusion is given in Section 5.

2 Theoretical Background and Hypotheses

It is pertinent to mention that theory always explains the *raison d'être* of a phenomenon. The theory is used in research to build a framework for the phenomenon under study and the basic purpose of a theory is to establish, define and elaborate the interconnection among the constructs being researched. The research could be designed to contribute to multiple theoretical viewpoints. It is therefore important for the researches which are interdisciplinary to be considered by theoretical perspectives of other domains for better understanding (Amundson, 1998). In the absence of institutional pressure, stakeholder's pressure alone cannot make companies assign resources for environmental management practices (Vanalle et al., 2017).

2.1 Stakeholder Theory

The stakeholder theory is a theory for managing the organization which contains diverse parties or members both internal and external that may impact by business entities like employees, suppliers, customers, and other institutions. This theory advocates morals and values in managing an

organization such as the conservation of environment or initiatives like a sustainable supply chain. Stakeholder theory proposes stakeholders who can affect an organization from achieving its objectives or could get affected by the achievement of an organization's objectives. It further extends the stakeholder concept and says that it could be an individual or group on which an organization is dependent for its continued survival (Freeman and Reed, 1983). Stakeholder theory proposes that organizations produce externalities that affect stakeholders and in return stakeholders exert pressure on organizations to minimize the adverse influences and increase the positive impacts. External environmental concerns from various stakeholders are deemed to be internalized through these stakeholder pressures within and between supply chain members (Sarkis et al., 2010). Stakeholder analysis for GSCM advocates that not all GSCM practices are beneficial for generating a competitive edge for the firms. There are quite many directions and developments in stakeholder theory but the basic principle says that there are external and internal groups which influence organizational practices (Sarkis et al., 2010)

2.2 Coordination Theory

An organization can be divided into three general constituents i.e. actors, goals and resources. The coordination theory is defined as a body of principles about how the activities of separate actors can be coordinated in a systematic way to achieve any goal. Coordination theory can both draw upon and contribute to work in many different fields including economics, sociology and organization theory (Malone, 1988). Coordination theory refers to how coordination could occur in diverse systems and that coordination is managing dependencies between activities to achieve a holistic objective (Malone and Crowston, 1994). Crowston (1998) argues that the coordination theory is still in the phase of development regarding the mechanism of prevailing coordination in extended kinds of systems. He further stresses on the point that, actors in a system are challenged with coordination difficulties which are resulted due to dependencies in the organization that limits the efficiency and effectiveness of process performance. Zhu et al. (2012) used a coordination theory-based approach in their research and suggested that the coordination of external and internal GSCM practices has resulted in a more satisfying performance in the overall supply chain. Research extends the GSCM theory development by incorporating a coordination theory standpoint in GSCM research. The coordination theory argues that enterprises should integrate activities along their supply chain. Moreover, it claims that the coordination of organizational activities like as internal and external dimensions of management practices will result in better performance outcomes in the supply chain.

Green supply chain contributes to intertwine and integrate environment factor into production, engineering, and logistics (Sarkis, 2006). In a coordinated supply chain focal firm is the decision-maker and through a network of relationships, superior performance is achieved on shared goals (Shah et al., 2008). There are limited researches that examine the internal and external coordination mechanisms holistically between intra-organizational and inter-organizational networks. In the absence of internal cooperation mechanisms inside the organization, the goal of superior performance achievement through external cooperation with supply chain partners can never be materialized. To address this issue coordination theory proposes that manufacturing companies have to streamline, align and coordinate internal and external activities to perform well, additionally to research in the new emergent field of green supply chain management stretching it beyond the technological domain will be fruitful (Zhu et al., 2012). After the extensive literature review following variable are selected within the context of theories.

Institutional Pressures: Chinese government-imposed environmental regulations and policies on manufacturers to promote GSCM and other corporate environmental practices primarily to increase exports and to attract foreign investment (Zhu, Sarkis, and Geng, 2005). Institutional pressures are one of the most important factors that encourage companies to adopt internal GSCM and the same influences the automotive suppliers to pursue GSCM practices (Vanalle et al., 2017). Firms have to adhere to institutional pressures that are exerted by external stakeholders on the firms.

Customer Monitoring: Customers have an important role in the implementation of internal GSCM practices by manufacturers (Laari et al., 2016). Firms adopt certifications (ISO 14001 or EMAS etc) in the result of the environmental monitoring of customers (Vachon, 2007). Customers are one of the most important stakeholders as firms are dependent on them for their survival and they most importantly influence the organizations to adopt a certain set of strategies.

IGSCM: Internal green supply chain management is defined as the environmental management practices steered within an organization. Coordination among all functional departments along with entire supply chain is the most important factor to implement these practice successfully (Rao and Holt, 2005; Vachon and Klassen, 2006; Zhu et al., 2008a; Zhu et al., 2008b). Internal GSCM involves practices such as ISO 14001 certification, an environmental audit of departments, eco-labeling of products manufactured, green procurement system, reduction

of greenhouse emissions, green product compliance data (Chien and Shih, 2007; Yu et al., 2014). Internal green supply chain management practices are exercised to curb the externalities and negative impacts of a firm to comply with stakeholder's pressures.

Supplier Monitoring: environmental performance is dependent upon effective and successful ecological monitoring which provides information necessary for the implementation of green sustainability programs throughout the entire supply chain (Green et al., 2012b). Firms are now increasingly tending towards managing their supplier's environmental performance to make sure that the products delivered are ecofriendly and made through green raw materials (Rao and Holt, 2005). Supplier monitoring shows the coordination between customers and suppliers in the context of internal and external green supply chain practices which also covers the aspect of external groups influencing the organization's practices.

Customer Collaboration: Suppliers and buyers need collaborative efforts to achieve environmental sustainability (Tachiwaza 2015). Collaboration among customers and suppliers is critical in the context of GSCM (Woo et al., 2016). By collaborating with customers shared a goal of achieving green practices in a coordinated supply chain is materialized.

Supplier Collaboration: Green suppliers are critical for establishing a green supply chain strategy and improved green performance (Woo et al., 2016). In a green supply, chain suppliers contribute to attaining environmental sustainability by using green raw materials and adhering to green programs (Yang, 2013). In an integrated green supply chain, a focal firm influences others to achieve shared goals.

Environmental Performance: It is the ability of manufacturing firms to curb down the hazardous air emissions, water, and solid wastage and reduced consumption of toxic materials (Zhu et al., 2008a). Lack of coordination in external green practices will weaken the environmental performance in manufacturing firms (Zhu et al., 2012). Upon external pressure of stakeholder's environmental performance is to reduce the negative impact of externalities which firm produces.

Financial Performance: A firm's financial performance is indicated by a reduction in wastages and reworks, improved productivity, increased return on assets (Fullerton et al., 2014). Green efforts improve the green and financial performance in a coordinated supply chain (Yang et al., 2013). Customer collaboration in combination with internal green practices is the most effective way to enhance financial performance (Laari et al., 2016).

Operational Performance: Increased demand of customers in environmental sustainability manufacturers required to adopt green practices which leads to operational performance improvement and will be a source of high-level customer satisfaction (Chavez et al., 2014). A proactive environmental management approach results in an improvement in the operational performance of a firm (Vachon and Klassen 2008). Internal environmental management activities and collaboration with both suppliers and customers will result in enhance and improved operational performance in terms of delivery, flexibility, cost and quality (Yu et al., 2014).

2.3 Hypotheses Development

2.3.1 Institutional Pressures and IGSCM

Organizations are operating in an environment where they have to face, counter and comply with multiple forces and pressures arising from various sources. Regulatory pressures exerted by the government are critical to comply with firms by adopting reactive internal environmental management practices (Zhu et.al, 2012). Firms usually dedicate the resources for implementing comprehensive environmental practices in the presence of strong institutional pressures (Vanalle et al., 2017). Institutional pressures from the important stakeholders as per stakeholder theory helps an organization to improve the compliance while transforming their conventional operations into environment-friendly (Sarkis et al., 2010). Organizations face the threat of legal action and penalties in case they failed to comply with environmental regulations (Sarkis et.al, 2010). In the light of stake-holder's theory, coercive or legitimate power is usually displayed by the institutions and external stake-holder possess to make the focal company comply with the environmental-friendly practices (Ahmed et al., 2019; Khan et al., 2019).

Various researchers empirically tested the impact of institutional pressures on organizations to adopt internal environmental and green practices found the relationship positive and significant (Zhu et al., 2013; Yang, 2017; Vanalle et al., 2017; Mohanty and Prakash, 2014). On the basis of the above research findings and empirical results we propose our first hypothesis as follows:

H1: Institutional pressures has a significant association with internal green supply chain practices.

Stakeholders are sometimes classified into two categories namely primary and secondary. Primary stakeholders are customers, suppliers, employees and investors and secondary stakeholders are media and other special interest groups (Clarkson, 1995). Stakeholder pressures are a great source of motivation for organizations to adopt green and environmental management practices (Buisse and Verbeke, 2003). Organizations decision to implement environmental management practices is affected by stakeholders like customers and clients (Sarkis et al., 2010). Customer's demand from their suppliers to implement proactive environmental practices (Zhu and Sarkis, 2004).

Monitoring is defined as a system that makes sure that suppliers are abiding by certain environmental commitments and to take corrective measures if required (Giovanni and Vinzi, 2014). It also involves other activities that involve the collection, evaluation, assessment and analysis of supplier information, supplier's environmental management and incoming products (Lee, 2008). Thus coordinated effort in lieu with coordination theory by customer to monitor the effective actions taken by the focal firm to enhance eco-friendly practices could be a helpful to serve the cause. Laari et al (2016) empirically examined the impact of customer monitoring on the implementation of internal green practices and found this relationship significant and positive. This notion is also supported by Klassen and Vachon (2003) where they found that there is a positive and significant relationship between customer-initiated evaluation and level of investments in environmental technologies. Giovanni and Vinzi (2014) also studied the effect of monitoring practices on suppliers GSCM practices and found that there is a positive and significant impact of monitoring practice on firms GSCM practices. Since the customer is an important stakeholder as per stakeholder's theory therefore, on the basis of the above discussion we propose the hypothesis as follows:

H2: Environmental monitoring by the customer has a significant association with internal GSCM practices.

2.3.1 IGSCM and Firm Performance

Diabat and Govindan (2011) state that there is an increasing tendency among organizations to embrace the fact that environmental management is of vital importance and have a long-term effect on organizational performance. Geng et al (2017) found in their meta-analysis that green supply chain practices lead to enhanced environmental, economic and operational performance. Initiatives to implement environmental management tend to improve environmental performance, financial performance and competitive advantage (Rao and Holt, 2005). As a part of system thinking approach, Zhu et al. (2012) advocates the coordination theory and urge that coordination of external and internal GSCM practices has resulted in a more satisfying performance in the overall supply chain.

Jabbour et al (2017) examined the influence of GSC practices on environmental performance and found that there was a strong and significant relationship among them. These results were supported by another study conducted by Laari et al (2016). Lee et al (2012); Lai and Wong (2011); and Yu et al (2014) conducted a study and found that the effect of internal green practices is positive and significant with operational performance. Chien and Shieh (2007); Huang et al (2017); Zailani et al (2012); and Ali et al (2017) examined the green supply chain practices and found that they are significantly associated with financial performance. Therefore, we postulate our hypothesis as follows:

H3 (a): Implementation of internal GSCM practices has a significant association with the operational performance

H3 (b): Implementation of internal GSCM practices has a significant association with the environmental performance

H3 (c): Implementation of internal GSCM practices has a significant association with the financial performance

2.3.3 IGSCM instigates External Green Practices

There is a need to shift from the arm's length approach to a more collaborative and cooperative approach between customer and supply chain to yield better results from environmental management (Preuss, 2005). Green supply chain integration logistically and

technologically is linked with monitoring and collaboration of primary suppliers and customers (Vachon and Klassen, 2006). To achieve external green collaboration within the supply chain network a firm must pursue internal green practices. According to the coordination theory, it requires coordinated efforts of different set of people or functions within the system to achieve a goal ((Malone, 1988).

An empirical study by Zhu et al (2013) suggests that supply chain functional eco-friendly practices both internal and external are significantly and positively correlated. Similarly, Laari et al., (2016) also found internal GSCM practices significantly affecting customer collaboration, supplier collaboration, and monitoring. Though both suppliers and customers have an integral role as per stakeholder theory however coordination and collaboration among them will eventually complement the GSCM (Zhu and Sarkis, 2004). Hence, we postulate our hypothesis as follows:

H4 (a): Internal green practices have a significant association with the environmental monitoring of suppliers

H4 (b): Internal green practices have a significant association with environmental collaboration with suppliers

H4 (c): Internal green practices have a significant association with environmental collaboration with customers

2.3.4 Influence of Environmental Performance on Financial Performance

Organizations adopt green practices in the quest to achieve environmental performance which also affects other performance measures like operations and finance as these all measures are interlinked in an organization. Optimization in internal functional performance is always been an outcome of coordinated efforts among the internal and external stake-holders. Attaining excellence in one measure certainly affects other measures as well. This will be the greatest motivation for an organization that in a quest to achieve environmental performance, they also attain operational and financial performance hence more profitability. This notion was supported by Green et al (2012a) as their study shows that environmental performance is significantly and positively associated with financial and operational performance in manufacturing concerns based in the US. Yang et al (2010) study shows that environmental performance has a positive effect on

operational performance in manufacturing firms. Fullerton et al., (2014); Yu et al., (2014) supported the notion that operational performance has a significant impact on financial performance. Hence, we propose our hypothesis as follows:

H5 (a): Environmental performance has a significant association with the operational performance

H5 (b): Environmental performance has a significant association with financial performance

H5 (c): Operational performance has a significant association with financial performance

2.3.5 Influence of Environmental Collaboration on Firm Performance

Vachon (2008) conducted research to analyze the environmental collaboration of a firm with its suppliers and customers and found that it has a positive and significant impact on operational performance. Yu et al (2014) also supported this in their study where they found GSCM with suppliers and customers are significantly and positively related to operational performance. In past studies, collaborations are an outcome of well-coordinated effort month the partners (Ahmed et al., 2019). For creating high level of synergies and collaboration, it is required to bring all the key stake-holders on the same page. Woo et al (2016) found that environmental collaboration is significantly associated with financial performance. This was also complemented by Corsten and Felden (2004) where they found the effect of supplier collaboration positive and significant with firm financial performance. Tachiwaza et al (2015) state in their test results that supplier monitoring is significantly related to supplier collaboration and supplier collaboration is significantly associated with environmental performance in the Spanish context.

Green Jr et al (2012b) studied environmental collaboration and monitoring impact on organizational performance where they found that environmental monitoring has a significant relationship with environmental performance. Giovanni (2012) also supported this in his study where he established that external environmental management is significantly associated with environmental performance. Laari et al (2016) study revealed that supplier monitoring is significantly associated with supplier collaboration and environmental performance while environmental collaboration with customers positively and significantly associated with financial performance. Since the performance cannot be improved without having the coordination among

the stakeholders as per coordination and stakeholder theory (Zhu et al., 2010; Zhu and Sarkis, 2004, therefore we establish our hypothesis as follows:

H6 (a): Environmental collaboration with customers has a significant association with environmental performance

H6 (b): Environmental collaboration with customers has a significant association with operational performance

H6 (c): Environmental collaboration with customers has a significant association with financial performance

H6 (d): Environmental collaboration with suppliers has a significant association with operational performance

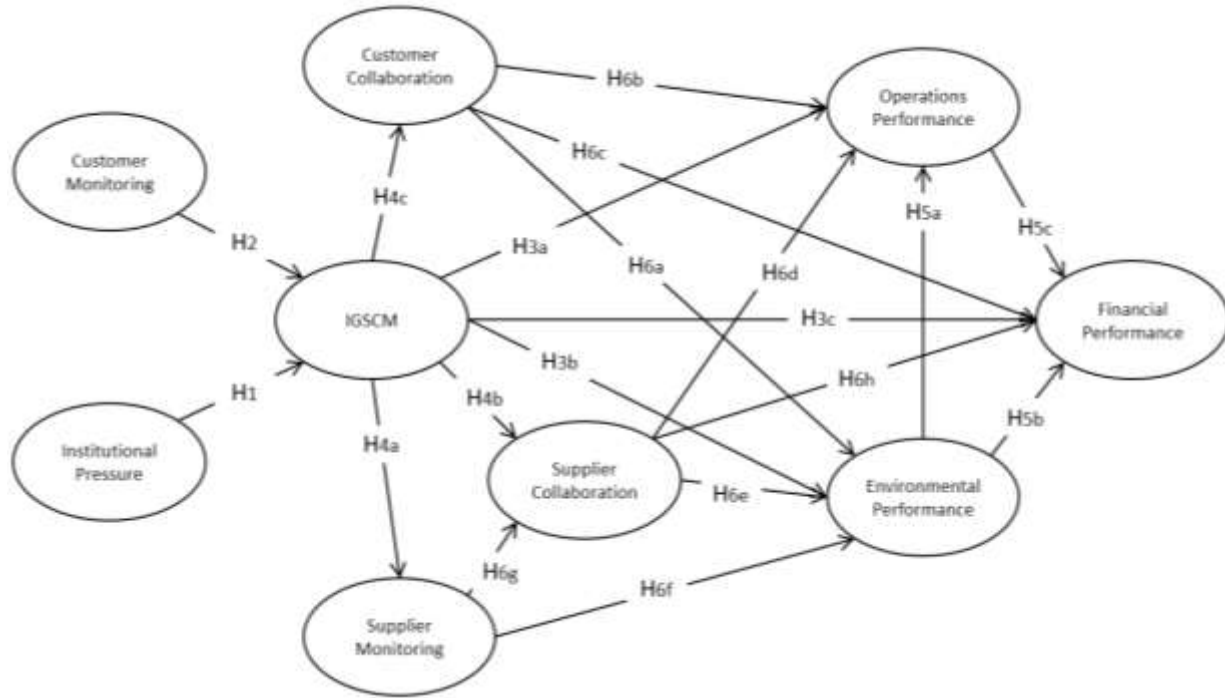

H6 (e): Environmental collaboration with suppliers has a significant association with environmental performance

H6 (f): Environmental monitoring of suppliers has a significant association with environmental performance

H6 (g): Environmental monitoring of suppliers has a significant association with environmental collaboration with suppliers

H6 (h): Environmental collaboration with suppliers has a significant association with financial performance

Figure 1 Research Framework

3. Research Methodology

The main purpose of this paper is to analyze the effect of institutional and stakeholder pressures on the adoption of green supply chain practices by manufacturing firms and how they propagate this pressure further upstream and downstream to their supply chain partners and the result of these green practices on their performance measures. The research approach used in this study is a quantitative approach to identify and analyze the effects and relationships between variables used.

3.1 Research design

In this study, we will use a correlational research design to check the relationships among the constructs by using statistical analysis. Correlational research design commonly used by researchers to analyze the relationship between the dependent and independent constructs. Here in this research, we observe the relationship among institutional pressures and stakeholder pressures with internal green supply chain practices, the relationship among internal green supply chain practices with supplier collaboration, supplier monitoring, customer collaboration, financial performance, environmental performance and operational performance by the correlational method.

3.2 Population, Sampling and Sampling Technique

Since the study focuses on environmental (green) supply chain management in the Pakistan manufacturing industry, the research population included all Pakistani manufacturing companies who were inactive operations at the time of the study. However, as a way of sampling, we focused on companies that are ISO 14001 certified in order to ensure the accuracy and generalizability of results. These companies were selected because they were viewed as haven gotten involved in programs that are in line with the subject under consideration (Zhu and Sarkis, 2004). There were 343 ISO 14001 certified companies in Pakistan in 2018 when this study was conducted (ISO Survey, 2016, "Laurent Charlet", para.3).

Respondents for this study were selected through purposive sampling technique, a non-probability sampling method and included supply chain managers holding the position of executive, senior officers, assistant managers, managers, general managers or directors in the ISO 14001 certified companies. Through the business directory, the ISO 14001 certified companies were identified and they were approached accordingly. Respondents are approached through online google-forms and in-person through personal links and references. In order to make the data, reliable position holders in supply chain management were chosen as they were knowledgeable in answering the questions about variables understudy in the context of their organization.

3.3 Sample Size and Data Collection

The sampling and sampling techniques resulted in a collection of 126 usable data from the target population, who worked as supply chain practitioners from ISO 14001 certified manufacturing companies in Pakistan. The survey questionnaire was used as a data collection instrument and composed of 58 items to measure performance outcome. All questions were answered using a 5-point Likert scale. Details of the constructs adapted and their sources can be found in Table 1. Details of the demographics of respondents are tabularized in table 2.

3.4 Issue of Endogeneity

Guide and Ketokivi, (2015) highlights the issue of causality in empirical research settings involving cross-sectional data. The issue of causality refers to a scenario where endogenous constructs in a research model also affect the exogenous construct accordingly. Therefore, as employed in the studies by Dubey et al., (2018; 2019) and Ahmed et al., (2019), nonlinear bivariate

causality direction ratio (NLBCDR) was computed. According to Kock (2018), the threshold value of NLBCDR is >0.7, which is found in the present study as 0.974.

Table 1 Variables and their Sources

Variable	Source
Institutional Pressure	Zhu et al. (2013); (DiMaggio and Powell, 1983); Ke et al. (2009), Liu et al. (2010), Huo et al. (2013), Zhu et al. (2013)
Customer Monitoring	Vachon & Klassen, 2006; Zhu et al., 2008; De Giovanni & Esposito Vinzi, 2012
Internal GSCM	Zhu et al., 2008; Yang et al., 2013
Environmental coll. with supplier	Vachon & Klassen, 2006; Zhu et al., 2008; De Giovanni & Esposito Vinzi, 2012

4. Results and Data Analysis

4.1 Overview

In this section, a detailed data analysis of the collected data in the study was completed. The objective is to analyze the pressures and influences on a focal firm internal green supply chain practices and internal green practices effect on performance measures along with upstream and downstream of a supply chain. Independent variables in this study includes institutional pressures (IP) and customer monitoring (CM) whereas internal green supply chain practices (IGSCM), customer collaboration (CC), supplier collaboration (SC), supplier monitoring (SM), financial performance (FP), operational performance (OP) and environmental performance (EP) are dependent variables.

Structural equation modeling (SEM) technique is used as it is highly precise (Hair et al., 2010). SEM uses different types of models to show the relationship between observed variables and to provide quantitative test of theoretical model (Shumaker & Lomax, 2010). PLS SEM has proven over the years to be more appropriate in dealing with complex models with considerably high number of indicators, constructs or relationships (Barclay, Higgins & Thompson, 1995; Garthwaite, 1994). In this research, PLS is used due to its predictive power and capability to handle complex model. This technique is suitable for small sample sizes and complex models (Hair et al., 2014; Peng & Lai, 2012). Data analysis is performed by using Smart PLS software as it is deemed most powerful SEM tool (Ringle et al., 2005; Chin, 1998).

4.2 Measurement, Outer Model

In this section reliability and construct validity of our research model is analyzed through discriminant validity, convergent validity and content validity details are mentioned in below sections.

4.2.1. Content Validity

Content validity of measurement items were assessed by using composite reliability. Values should be greater than 0.7 to be adequate (Nunnally & Bernstein, 1994; Fornell and Larcker 1981). Items which have higher loading on other constructs were removed. Results are mentioned in Table 3 where all the items have loading more than 0.7, which indicate strong, factor loadings

Table 3: Factor Loading Significant

Constructs	Code	Items	Loadings	Standard Deviation	T Statistics	P Values
CC	CC1	<i>We have worked together with our customers to take environmental issues into account in product design.</i>	0.804	0.056	14.325	0.000

SM4	<i>We have demanded our suppliers to implement an environmental management system (e.g. ISO 14000)</i>	0.872	0.030	28.985	0.000

4.2.2 Convergent Validity

In order to ensure convergent validity, it is required to confirm that construct items that are theoretically related to each other must be related to each other after the data analysis. We can ensure this by using three types of methods namely factor loadings, composite reliability and average variance extracted (Haier et al., 2010). In the factor loading section, we consider the factors relevant which are highly loaded i.e. equal to or more than 0.7 and statistically significant. In the second step, we see composite reliability which indicates how consistently the items seek to specify the latent constructs (Hair et al., 2010). Values which are ideally accepted for composite reliability is 0.7 (Hair et al., 2010; Fornell & Larcker 1981). It is evident in Table 4 that composite reliability values are ranging from 0.883 to 0.944 which are quite above the recommended and prescribed values.

In the third step, we will check the average variance extracted, it is defined as a level of common variance between the indicators of the latent construct (Hair, Anderson, Tatham & Black, 1998). The value of the average variance extracted ideally be more than 0.5 (Fornell & Larcker, 1981; Hair et al., 2010). It is quite evident from Table 4 that our values of average variance extracted are between 0.579 to 0.807 which are according to the prescribed level. Hence from all three methods checked convergent validity has been established.

Table 4: Convergent Validity

	Composite Reliability	Average Variance Extracted (AVE)
CC	0.922	0.703
CM	0.896	0.684
EP	0.883	0.655
FP	0.944	0.807
IGSCM	0.907	0.709
IP	0.906	0.579

OP	0.918	0.651
SC	0.920	0.658
SM	0.916	0.732

4.2.3 Discriminant Validity

In this section, we discuss discriminant validity which is the measure to check how a set of measurement items differentiate a variable from other variables in a research model. In other words, the measures which are should not be related to each other are in actual do not found to be linked with each other after data analysis conducted. In order to make sure the discriminant validity square root of the average variance extracted is analyzed with correlations between the constructs of research (Chin, 2010; Fornell & Larcker, 1981). We can see from Table 5 that diagonal line values are greater than other values in their respective rows and columns that establish the discriminant validity. Another way to confirm discriminant validity is the heterotrait-monotrait ratio of correlations (HTMT) estimates which should not be more than 0.85 (Henseler, Ringle and Sarstedt, 2015). Value in Table 6 shows that they are well below 0.85 hence establishing the discriminant validity.

Table 5: Discriminant Validity (Fornell-Larcker)

	CC	CM	EP	FP	IGSCM	IP	OP	SC	SM
CC	0.838

4.3 Structural Model and Hypothesis Testing

As we have checked and established the goodness of fit for the outer model in the previous section now we will scrutinize the standardized path coefficients to test the postulated relationships established in this study. Software used for this purpose is SmartPls 3.2.4 (Ringle, Wende and Becker, 2015). To check the statistical significance of path coefficients, the bootstrapping technique is used in this research (Chin 1998; Tenenhaus et al., 2005; Haenlein and Kaplan, 2004; Efron & Tibshirani 1986). Results of path analysis are summarized in Figure 2

*~ $p < 0.05$; **~ $p < 0.01$; ***~ $p < 0.001$

Figure 2 Path Model Results

4.3.1 Predictive relevance of the model

The predictive power of factors is examined via R square and Q square (Cross-Validated Redundancy). The value of R square higher than 26% is deemed significant (Cohen, 1998). In Table 7 we can see that 47.5% of internal green supply chain (IGSCM) is explained by customer monitoring and institutional pressures; 43.5% of customer collaboration is explained by internal green supply chain management; 51.4% of supplier monitoring is explained by internal green supply chain management; 43.2% of supplier collaboration is explained by supplier monitoring and internal green supply chain management; 57% of operational performance is defined by internal green supply chain management along with supplier collaboration. Environmental performance and customer collaboration; 48.8% of environmental performance is defined by internal green supply chain management along with customer collaboration. Supplier monitoring and supplier collaboration; 46.4% of financial performance is defined by customer collaboration,

environmental performance, supplier collaboration, and internal green supply chain management. These results indicate that the factors used in this study are highly predictive.

The second method to check the model's predictive quality is cross-validated redundancy measure which is also called Q square (Hair, Sarstedt, Ringle & Mena, 2012; Geisser, 1974; Stone, 1974). Cross-validated redundancy measure is tested by blindfolding technique in SmartPLS with omissions distances at 5. This method is customized to estimate the parameters by not including some of the data and handling them as missing values (Fararah & Al-Swidi, 2013). Q square values greater than 0 shows that the model has predictive significance. In Table 7 we can also see the Q square values for customer collaboration is 0.266, for environmental performance its value is 0.276, for financial performance its value is 0.323, for internal green supply chain management its value is 0.290, for operational performance its value is 0.307, for supplier collaboration its value is 0.244 and for supplier monitoring its value is 0.332. All these values confirm that model fitness is good and the model has good prediction quality.

Table 7– Predictive Power of Constructs

	R Square	Q²
CC	0.435	0.266
EP	0.488	0.276
FP	0.488	0.340
IGSCM	0.475	0.290
OP	0.573	0.308
SC	0.432	0.244
SM	0.514	0.332

5. Conclusion

5.1 Summary and Theoretical Implications

The main emphasis of this paper is to evaluate what triggers the internal green supply chain management practices in manufacturing firms operating in Pakistan. This research takes a holistic approach to assess the impact of internal green supply chain practices by including upstream and downstream channels of a focal firm and fills the gap identified by Tachiwaza et al. (2015) and Dai, Cantor & Montabon (2017). Further, it also fills the gap identified by Geng et al

(2016) and Vanalle et al (2017) by conducting this research in less explored emerging Asian economies. Our research addresses the call from Geng et al (2016) to examine the green supply chain management from a theoretical lens. The results validate the stakeholder theory whereas the coordination theory is also supported to a great extent. It is observed that customer monitoring and institutional pressures have a positive and significant effect on internal green supply chain practices. It shows that green practices are triggered by stakeholder and regulatory pressures. This finding is in line with Chavez et al., (2016); Yang (2017); Lee (2008); Vanalle et al (2017); Laari et al (2016) which concluded that close monitoring of customers' demand and expectations and mechanism to have updated customers' information results in improvement in internal processes and accordingly green practices. As internal green supply chain practices triggered off by customer monitoring and institutional pressures their impact is found positive on customer collaboration and supplier monitoring. These results show that internal green practices are closely linked with customer collaboration and supplier monitoring in the downstream and upstream respectively. These significant results are in line with Laari et al (2016). Interestingly internal green practices have no significant impact on supplier collaboration. Our results show that in the context of Pakistan supplier monitoring is a more appropriate and significant approach to implement and propagate green practices in upstream of the supply chain than collaboration with a supplier. This may be due to the implementation of green practices that are in the infancy stage in Pakistan which makes the monitoring approach more effective. Internal green supply chain management practices are positively and significantly impacting environmental and operational performance. This authenticates the work of (Chien and Shih, (2007); Ali et al (2016); Giovanni, (2012); Huang et al (2017); Yu et al (2014) which also endorsed that by improving IGSCM organizations can improve their operational efficiencies by reducing wastes and in result it impacts positively on environmental performance. Results indicate a positive and significant relationship between internal green supply chain management practices, environmental and operational performance but IGSCM has no significant impact on financial performance, as internal green practices implementation do incur a cost. It is plausible that results found no significant relationship between them. Laari et al (2016) also found no significant relationship between internal green supply chain management and financial performance.

On the downstream side, it is observed that collaborating with customers results in a positive impact on operational, environmental and financial performance. These results

substantiate the work of (Corsten and Felde (2005); Chavez et al (2014); Tachiwaza et al., (2015); Yang et al (2013) whose studies are aligned with this finding of present study and that is customer collaboration and frequent interactions along with firms' capabilities to absorb customers' opinion and work closely with them often reap better operational, environmental and financial performances. It is noted that the effect of environmental performance is complementary to operational performance which is in line with the work of (Green et al., 2012a) but has no effect on financial performance. Laari et al., (2016) also found no impact of environmental performance on financial performance in their research. Operational performance is relating to financial performance and has a significant impact on it which compliments the work of Fullerton et al., (2014). It also fulfills the call of Laari et al (2016) to examine the effect of internal green supply chain management on operational performance and operational performance impact on financial performance. As internal green supply chain management has a complementary effect on supplier monitoring. Consequently, supplier monitoring has a positive and significant effect on supplier collaboration which authenticates the work of Tachiwaza et al (2015) and also has a cogent effect on environmental performance which validates the work of Green et al (2012b). It was postulated that supplier collaboration has a positive effect on operational performance, environmental performance and financial performance. But it was found that supplier collaboration has no effect on operational performance which was also the case in the research by Hollos et al (2012). Supplier collaboration also has no effect on environmental performance. Laari et al (2016) also found no support for supplier collaboration's significant impact on environmental performance, while it has a significant effect on financial performance which substantiates the work of Corsten and Felde (2005). Overall results indicate that Pakistani manufacturing firms find supplier monitoring a preferred and effective approach than supplier collaboration to implement green practices and to achieve environmental performance.

5.2 Theoretical Implications

This study provides three theoretical contributions to enhance the literature of green supply chain management. First, most of the results of this study are found to be consistent with the previous researches which are performed to explain or explore the coordinated efforts of various

stake-holders having different research model for instance (Ahmed et al., 2018; Ahmed et al., 2019; Hollos et al (2012) and Zhu et al (2013 Laari et al (2016). Lee et al (2012); Lai and Wong (2011); and Yu et al (2014). This consistency in results enhances the rigor in the use of stakeholder aligned with system/coordinated theory in GSCM. Second, studies prior to this limit the smaller frameworks which are good to keep the focus of the study on a specific area but this study uses the comprehensive research model to understand the holistic behavior of supply chain members in achieving the common goal of improving environmental and economic performance. Third, this research provides a framework explains the contributions of stakeholders and then its impact on firm performance. This may be helpful to academicians and researchers to further extend their research on similar lines. Thus through the outcome of this research, it is evident that institutional and stakeholder pressures are effective in persuading companies to adopt green practices. While systematic coordination in the shape of collaboration and monitoring enhances the firm green performance.

5.3 Managerial Implications

It is evident from the findings of this study that institutional and stakeholder pressures are effective in persuading companies to adopt green practices. There is a need for government and other stakeholders to increase their magnitude of pressure on firms operating in Pakistan to make them comply with this external pressure and adopt green supply chain management practices for the betterment of the environment. To respond and comply with external pressures to adopt green supply chain management, focal firms have to collaborate with its customers and monitor its suppliers to further transfer the pressure in the supply chain to achieve the wholesome effect. Internal green supply chain management has an impact on supplier collaboration but through supplier monitoring. On performance measures, internal green supply chain management has a positive effect on operational and environmental performances which means the stronger the internal green practices, the better these two performance measures will be. This is a morale

booster for managers in manufacturing firms in Pakistan that by making your supply chain greener your firm will achieve excellence in environmental and operational performance. On the contrary internal green supply chain management not improving the financial performance which is understandable as green environmental practices do cause an increase in short term costs but in the long run, they will achieve the financial competitiveness (Woo et al., 2015). Another important dimension in performance measure is that collaborating with a buying firm will achieve excellence in all three performance measures i.e. environmental performance, financial performance, and operational performance. While collaborating with suppliers gets good financial performance. It is also pertinent to note that supplier monitoring which is the effective approach in Pakistani context has a complementary effect on environmental performance, therefore, it is highly recommended for managers in Pakistani manufacturing firms to adopt supplier monitoring as their focal approach (Laari et al., 2017).

5.4 Limitation of the study & future research directions

Even though this study makes considerable contributions to theory and practices, but more researches are required in a similar direction to have an in-depth understanding of the phenomenon. For future studies in this area may focus on the specific industry or sector like pharmaceutical, automobile, textile, etc. in order to be more specific in providing policy implications. Institutional pressure can further be broken down into factors like normative, coercive, and mimetic pressures which may provide further insights. This study is conducted in the context of Pakistani manufacturing industries with a small sample size which limits the generalizability of the results. Moreover, the present study employs data from ISO 14001 certified companies only, therefore study having non-certified companies may generate different results. Finally, testing the mediating relationship among variables will be useful to comprehend the indirect effects of the variable.
