ABSTRACT

MODELLING AND CONTROL OF DIELESS WIRE DRAWING

Yuandan Xie

A novel technique of drawing wire, i.e., dieless wire drawing, is described in which no conventional reduction dies are used. The wire is passed through a unit having stepped parallel bores filled with polymer melts, the smallest bore diameter being greater than the initial nominal wire diameter. The technique eliminates the need for a leader wire, prevents breakage during start-up, and eliminates the use of conventional reduction dies and, hence, the problem of die wear.

An analysis has been developed for predicting the produced wire sizes for given drawing speeds, the pressure distribution within the unit and the drawing load during the drawing process. The performance of the drawing process is effected by means of the plasto-hydrodynamic action of the polymer melt within the unit. Heat is generated by mechanical dissipation during the drawing process. The effect of this upon the performance of the process is considered by coupling the energy equation into the analysis and allowing the polymer viscosity to be dependent on temperature. Agreement between the theory and experiment is found to be close. To further investigate the performance of the drawing process, an extensive experimental study has been undertaken, in which parameters such as drawing speeds, the temperature of the polymer and type of polymers are varied.

Based on the theoretical and experimental results, a microcomputer-based control system for the dieless wire drawing process has been designed and built. A method with which the percentage reduction in area of the wire can be measured on line is proposed. Wires of desired qualities in terms of consistency in diameter over long lengths, or uniform change in area of the wire, are capable of being produced from the new system.

A self-tuning controller for deterministic systems is proposed, which has the same structure as a conventional PID controller. The new self-tuning PID controller is based on a generalised self-tuning controller with pole assignment for deterministic systems. Simulation and experimental studies for several examples indicate that the new controller performs well and can be further improved to provide a fundamental method of tuning a PID controller.

CHAPTER 1 : Introduction

1.1 - The Wire Drawing Process

1.2 - The Dieless Wire Drawing Process

1.3 - Background Development Leading to the Design of the
Microcomputer-Based Control System and the Scope of the Present
Work.

1.1 - The Wire Drawing Process

In the conventional wire drawing process, the reduction is achieved by pulling the wire through a tapered die. The die in this case acts primarily to reduce the wire diameter to a specific size, with an acceptable surface finish. Normally a die has a trumpet shaped bore, with a conical portion which serves to deform the wire. The minimum bore size of the die is always smaller than the inlet wire diameter. The possible reduction in area at each die may vary from 10 to 45 percent.

In wire drawing practice, lubrication is used to reduce the drawing load and die wear and hence improve the machine life and surface finish of the product. Generally two types of lubrication methods are used in wire drawing depending upon the material and the size of the wire. These are:

i) "Wet Drawing", in which the entire apparatus is submerged in a bath of lubricant. This type of lubrication is usually employed for wire diameter of less than 0.5 mm.

ii) "Dry Drawing", in which the wire is passed through a box of soap powder before entering the die. To facilitate the pick up of soap powder, the wire is passed through lime, borax or other alkaline substances. Dry drawing is usually used for wire diameters of more than 0.5 mm.

In conventional wire drawing, friction between the wire and the die is of the boundary type where metal to metal contact takes place in spite of the presence of a lubricant, resulting in die wear. Boundary lubrication methods have been used for the wire drawing process since the inception of the process itself. However, the tasks of producing satisfactory physical properties of the drawn wire to meet the demand for increased production and quality of product are proving to be beyond the scope of these traditional lubrication methods. Therefore, attempts

have been made to introduce other means of lubrication and to develop a more theoretical background to the process enabling greater understanding of the mechanisms involved, leading to improved and more efficient systems.

The hydrodynamic lubrication system was first introduced by Christopherson and Naylor [1]. In this system, a long close-fitting tube was placed before a conventional die. Oil was used for lubrication, and as the wire was pulled through the die, it pressurized the lubricant by viscous action. Experimental results showed that hydrodynamic lubrication was achieved under the designed conditions. It was necessary, however, to provide a leader to the full size wire in order to induce effective lubrication at the starting condition. The pressure nozzle had to be placed vertically and was of such a length that the wire industry found it too inconvenient to put it into practice. Also some die wear was still present. Modification to the above hydrodynamic system and other designs of lubricating system have been considered; for example, the combined hydrostatic and hydrodynamic lubrication and the double-die system [2], [3], [4]. However, the problem of breakage during start-up and the need for a leader to the full wire size was not solved by these designs.

1.2 - The Dieless Wire Drawing Process

A novel technique of wire drawing, i.e., dieless wire drawing, has been invented by Dr. G. R. Symmons and Dr. M. S. J. Hashmi, in which no conventional reduction dies are used and polymer melts are introduced as the lubricant in the drawing process [5].

The main feature of this technique is that the conventional dies are replaced by a dieless reduction unit (DRU) to reduce the wire diameter. Two types of DRU, one of tapered bore and the other of stepped

bore, have been designed and manufactured. Fig. 1.1 shows the details of both these units, in each case the smallest bore size of the DRU is always greater than the diameter of the undeformed wire.

The pulling action of the wire through the bore filled with viscous fluid gives rise to drag forces and generates hydrodynamic pressure; thus an effective die is generated. The combined effect of this hydrodynamic pressure and the drag force initiates plastic yielding and permanent deformation to the wire. The magnitude of the deformation depends on the performance of the viscous fluid, the geometrical configuration of the orifice and the drawing speed. It has been shown that reductions in cross-sectional area in excess of 20 percent may be obtained in a single pass when a wire (copper, mild steel or stainless) is pulled through the DRU filled with polymer melt. With a multi-unit drawing system higher deformations can be obtained. The polymer melt, in addition to acting as a lubricant, is also found to form a coating on the drawn wire. This coating is thought to be useful in protecting the wire against corrosion and also as a lubricant during any subsequent forming operation, e.g., bending or cold heading.

This technique has been useful in a number of ways in solving the problems associated with the conventional wire drawing process; e.g., die wear, initial wire breakage and the need for a leader wire. Since the diameter at the exit end of the DRU is greater than that of the wire, there is no metal to metal contact, and hence wear is no longer a problem. As no conventional reduction die is used, the need for a leader wire and breakage during start-up are also eliminated.

Fig.1.1 a) Stepped Bore Reduction Unit Assembly
b) Tapered Bore Reduction Unit

1.3 - Background Development Leading to the Design of the Microcomputer-Based Control System and the Scope of the Present Work.

Previous results from both theoretical analyses and practical tests in references [5], [6] and [7] show that, in the dieless wire drawing process, the reduction in area of the wire is affected by several factors. These are mainly the drawing speed, the performance of the

polymer used as pressure medium, the temperature of the polymer melt and the configuration of the DRU. The reduction of the wire is very sensitive to the drawing speed and the temperature of the polymer melt within the DRU. The results suggest that not only can normal wire of a uniform diameter be produced, but also that tapered wire with a uniform change in cross-sectional area of the wire can be produced by this drawing process. An application of this is the production of fine steel tapered wire for the manufacture of long wire ropes with a uniform change in cross-sectional area as used in deep sea mining.

Since the quality of the product is of utmost importance, methods of controlling the process must be developed in order to produce wires of desired qualities in terms of consistency in diameter over long lengths (for normal wire), or uniform change in area of the wire with a given rate (for tapered wire).

A theoretical investigation of the effect of the drawing speed and the temperature of the polymer melt within the DRU on the performance of the dieless wire drawing process must be undertaken in order to provide a greater understanding of the process. To further investigate the process, it is necessary to carry out an extensive range of experiments, in which parameters such as drawing speed, the temperature of polymer melt and polymers are varied. The results from the analysis and the experiments will be essential for designing a control strategy for the process.

A microcomputer-based control system is needed to ensure the required product qualities. Such a system can be made very flexible, and programmed to control the drawing process automatically. The operator inputs the specification via a keyboard, following a series of prompts on the computer screen. The control scheme is designed to produce the desired products with very high accuracy. Since the controlled variable

is the reduction in area of the wire, a transducer which can measure the reduction in area of the wire during the drawing process is required for a closed-loop control system.

A digital PID controller could be used to implement the control system with parameters tuned according to existing methods. However, because the majority of controllers used in industry are PID and because some disadvantages are associated with conventional PID tuning techniques, providing a procedure to automatically generate PID tuning parameters instead of the usual trial-and-error procedure is a problem whose importance in engineering practice may not be overestimated. An adaptive algorithm is required, and must be directed towards providing the field engineers with the capability to meet the needs of increasingly stringent control objectives. This is evidenced by the recent release of some PID self-tuning controllers in the market. Shortcomings in these designs have prompted the study of alternative methods of designing a self-tuning PID controller. In this work, a new PID self-tuning controller for a deterministic system, based on the generalised self-tuning controller with pole assignment, is proposed.

The objectives of the present work are therefore as follows:

1. To provide an improved theoretical analysis of the dieless wire drawing process and to investigate its performance by extensive practical tests. Upon the analysis and experimental results, a control strategy can be established.
2. To build a microcomputer-based control system for the dieless wire drawing process and to examine the product qualities from the new drawing process.
3. To provide a new adaptive controller which may also be used for tuning digital PID controllers.

CHAPTER 2 : Analysis of the Wire Drawing Process Using a Dieless Reduction Unit

2.1 - Introduction

2.2 - Review of the Previous Analyses

2.1 - Introduction

This chapter presents a theoretical analysis of the dieless wire drawing process, i.e., a static model of the process rather than a dynamic mathematical model of the process in control terminology. In this model, based upon mechanical principles, investigation of the effect of drawing speed and the temperature of the polymer melt within the DRU on the performance of the process are undertaken. The results of the analysis are essential for designing a control strategy for the process. The development of the dynamic mathematical models and, further, the Laplace transfer functions of the process, will be presented in chapter 3.

2.2 - Review of the Previous Analyses

Since this novel technique of wire drawing was invented by Dr. G. R. Symmons and Dr. M. S. J. Hashmi, in which no conventional reduction dies were used and polymer melts were introduced as the pressure medium in drawing process, various theories concerning the dieless wire drawing process have been developed.

Dr. Symmons and Dr. Hashmi first developed a Newtonian plasto-hydrodynamic analysis for a stepped bore reduction unit. In this the pressure medium of the polymer melt was assumed to have a Newtonian fluid behaviour and the deformation profile of the wire within the unit was assumed to be a function of distance squared [6]. Theoretical results enabled them to predict the percentage reduction in area, the pressure of the polymer melt within the unit and the axial stress in the wire. Although these were in close agreement with those observed experimentally at lower drawing speeds, the theory was found to be inadequate at drawing speeds in excess of about 1.2 ms^{-1} . For example,

experimental results showed that the percentage reduction in area increased with an increase in drawing speed, and reached a maximum magnitude of about 25 percent corresponding to a drawing speed of 1.2 ms^{-1} . Thereafter, the percentage reduction in area decreased when drawing speed was increased further. However, unlike the experimentally observed results, the theoretically calculated reduction in area always kept on increasing with an increase in drawing speed.

Later, Dr. Hashmi and Dr. Symmons presented a mathematical model for wire drawing through a conical orifice reduction unit filled with polymer melt, in which the polymer melt was assumed to be a Newtonian fluid and the deformation of the wire was assumed to take place in a linear profile [8]. A further development [9] presented a more precise numerical solution for wire drawing through a conical orifice unit. In their studies, the viscous fluid was assumed to be Newtonian and the continuum was assumed to be rigid non-linearly strain hardening. Finite difference numerical techniques were applied to solve the equations for the plasto- hydrodynamic pressure and the resulting axial stress which, in turn, enabled prediction of the non-linear deformation profile of the continuum and the reduction in area for a given drawing speed. Unlike the previous analyses, the need for an assumed deformation profile was eliminated. This analysis produced good correlation with experimental results at lower drawing speeds. However, the agreement between the experimental and theoretical results was still poor at higher drawing speeds. Several factors might contribute to the discrepancy between the theoretical and experimental results. Mainly, the polymer melt did not behave like a Newtonian fluid.

Dr. H. Parvinmehr presented a Non-Newtonian plasto-hydrodynamic analysis of the wire drawing process for a stepped bore reduction unit [7]. The effects of shear rate and pressure on the viscosity of the

polymer, together with the limiting shear stress, were included in the analysis. Strain hardening and strain rate sensitivity of the wire material were incorporated in the solution. Finite-difference numerical techniques were used to solve the relevant equations. The Non-Newtonian results showed a generally close agreement compared with the experimental results. However, the curve indicating the changes of percentage reduction in area versus drawing speed appeared to have a point at which the direction of the curve changed abruptly; i.e., a cusp appeared in the curve, which did not appear in the experimental results.

In the present study, a Non-Newtonian plasto-hydrodynamic analysis of the wire drawing process is presented for a stepped bore reduction unit. The effect of temperature on the viscosity of the polymer melt and the energy equation predicting the increasing in temperature during the wire drawing process are introduced into the analysis.

The present study predicts the percentage reduction in area, drawing load in the wire and the pressure of the polymer melt within the unit against drawing speed. The theoretical results agree well with those observed experimentally throughout the range of drawing speeds.

2.3 - Theoretical Analysis

When wire is pulled through the viscous polymer melt within the DRU, shearing takes place at the interface between the melt and the wire. This shearing action gives rise to a drag force on the wire and generates hydrodynamic pressure, the magnitude of which depends upon the speed with which the wire is pulled, the viscosity of the polymer melt and the geometrical configuration of the orifice which contains the melt. The combined effect of this hydrodynamic pressure and the drag force may initiate plastic yielding and cause permanent deformation to the wire itself.

During the wire drawing process, energy is dissipated mainly in two ways: through the action of viscous "friction" and through deformation. These sources will generate heat. Because the heat conductivity of the polymer melt used in wire drawing process is substantially low, the small amount of heat can not be transferred outside and will cause the temperature within the polymer to increase significantly. The change of the temperature, in turn, changes the viscosity of the polymer melt which, in turn, changes the dissipation as well as the shear stress, the pressure and thus the reduction in area. So we must indeed consider the thermal energy coupled with the plasto-hydrodynamic process.

In this section an attempt to analyse theoretically the deformation process taking place within the DRU is described. The effect of the thermal energy generated by viscous "friction" in the drawing process will also be taken into consideration. The results of the analysis tend to be very similar to the experimental results both at slower speeds and at higher speeds, and show better agreement than previous results.

The following theoretical analysis of deformation process which takes place within the DRU is based on the geometrical configuration of the stepped bore reduction unit as shown in Fig. 2.1a. To formulate the analysis the following assumptions were made:

- i) Flow of polymer melt is axial and laminar
- ii) Thickness of the polymer layer is small compared with the dimensions of the stepped bore
- iii) The pressure in the fluid is uniform in the thickness direction at any point along the length of the unit, that is $P = P(X)$ only.
- iv) The viscosity-temperature dependence is given by the equation

$$(\text{Appendix 1}), \quad \mu = \mu_0 e^{-aT} \quad (2.1)$$

where, μ is the viscosity of the polymer melt

μ_0 is the melt viscosity for a given polymer at reference temperature

"a" is a constant indicating the temperature dependency of the melt viscosity for a given polymer

T is the temperature variation of the polymer melt from the reference temperature

- v) The deformation profile in the deformation zone within the unit may be described by

$$Y = R_1 - bx^2 \quad (\text{see Fig. 2.1a})$$

Where $R_1 = D_1/2$ the initial radius of the wire.

- vi) The temperature in the fluid is constant along the drawing direction, but varies across the section of the polymer, that is $T = T(Y)$ only.

The analysis is presented in four parts:

2.3.1 - Determination of the Pressure in the Unit and the Axial Stress in the Wire Prior to Deformation of the Wire.

2.3.2 - Prediction of the Position of Yield of the Wire Inside the Unit.

2.3.3 - Energy Equation Applied to the Process.

2.3.4 - Prediction of Deformation Profile in the Deformation zone.

2.3.1 - Determination of the Pressure in the Unit and the Axial Stress in the Wire Prior to Deformation of the Wire

The pressure in the unit prior to deformation of the wire

Starting with the fundamental equations

$$\frac{\partial P}{\partial X} = \frac{\partial \tau}{\partial Y} \quad (2.2)$$

and

$$\tau = \mu \frac{\partial u}{\partial Y} \quad (2.3)$$

Where $\frac{\partial P}{\partial X}$ is the pressure gradient within the gap

τ is the shear stress

u is the velocity of the polymer melt at a distance Y from the
surface of the wire within the gap

μ is the viscosity of the polymer melt

Substituting for τ from equation (2.3) in equation (2.2) gives

$$\frac{\partial P}{\partial X} = \frac{\partial}{\partial Y} \left(\mu \frac{\partial u}{\partial Y} \right) \quad (2.4)$$

Integrating equation (2.4) with respect to Y , we have

$$\frac{\partial u}{\partial Y} = \frac{1}{\mu} \frac{\partial P}{\partial X} Y + \frac{C_1}{\mu} \quad (2.5)$$

Noting that P and $\frac{\partial P}{\partial X}$ are assumed to remain constant across the gap, and
since $T = T(Y)$, from equation (2.1) it can be seen that μ is the
function of Y . Integrating equation (2.5) gives

$$u = \frac{\partial P}{\partial X} \int_0^Y \frac{Y'}{\mu(Y')} dY' + C_1 \int_0^Y \frac{dY'}{\mu(Y')} + C_2 \quad (2.6)$$

Applying the boundary condition $u = U_0$, at $Y = 0$ gives

$$C_2 = U_0$$

Where U_0 is the velocity with which the wire is being pulled.

The flow of polymer melt in the stepped bore reduction unit is
divided into two sections, the first section being the entry part of the

unit before the step and the second section being the tube after the step. Applying the boundary condition for the first part that $u = 0$ at $Y = h_1$, and substituting for C_2 in equation (2.6), we have

$$\left(\frac{\partial X}{\partial P}\right)_1 \int_0^{h_1} \frac{Y'}{\mu(Y')} dY' + C_1 \int_0^{h_1} \frac{dY'}{\mu(Y')} + U_0 = 0 \quad (2.7)$$

Define

$$J_0 = \int_0^{h_1} \frac{dY'}{\mu(Y')} \quad (2.8)$$

and

$$J_1 = \int_0^{h_1} \frac{Y'}{\mu(Y')} dY' \quad (2.9)$$

Then from equation (2.7), we have

$$C_1 = - \frac{U_0 + \left(\frac{\partial P}{\partial X}\right)_1 J_1}{J_0} \quad (2.10)$$

which we assume to be known.

The flow of the polymer melt in the direction of pull in the first section of the unit is given by

$$Q_{X_1} = \int_0^{h_1} u dY \quad (2.11)$$

Substituting for u from equation (2.6) in equation (2.11) gives

$$Q_{X_1} = \left(\frac{\partial P}{\partial X}\right)_1 \int_0^{h_1} \int_0^Y \frac{Y'}{\mu(Y')} dY' dY + C_1 \int_0^{h_1} \int_0^Y \frac{dY' dY}{\mu(Y')} + \int_0^{h_1} U_0 dY \quad (2.12)$$

Referring to Appendix 2, the first term of equation (2.12)

$$\begin{aligned}
\left(\frac{\partial P}{\partial X}\right)_1 \int_0^{h_1} \int_0^Y \frac{Y'}{\mu(Y')} dY' dY &= \left(\frac{\partial P}{\partial X}\right)_1 \int_0^{h_1} \int_{Y'}^{h_1} \frac{Y'}{\mu(Y')} dY dY' \\
&= \left(\frac{\partial P}{\partial X}\right)_1 \int_0^{h_1} (h_1 - Y') \frac{Y'}{\mu(Y')} dY' \\
&= \left(\frac{\partial P}{\partial X}\right)_1 (h_1 J_1 - J_2)
\end{aligned} \tag{2.13}$$

Where $J_2 = \int_0^{h_1} \frac{Y^2}{\mu(Y)} dY$ (2.14)

The second term

$$\begin{aligned}
C_1 \int_0^{h_1} \int_0^Y \frac{dY'}{\mu(Y')} dY &= C_1 \int_0^{h_1} \int_{Y'}^{h_1} \frac{dY'}{\mu(Y')} dY' \\
&= C_1 \int_0^{h_1} \frac{(h_1 - Y')}{\mu(Y')} dY' \\
&= C_1 (h_1 J_0 - J_1)
\end{aligned} \tag{2.15}$$

The third term

$$\int_0^{h_1} U_0 dY = U_0 h_1 \tag{2.16}$$

Equation (2.12) in combination with equations (2.13) to (2.16) gives

$$Q_{X1} = \left(\frac{\partial P}{\partial X}\right)_1 (h_1 J_1 - J_2) + C_1 (h_1 J_0 - J_1) + U_0 h_1 \tag{2.17}$$

The continuity equation for this case gives

$$\frac{\partial}{\partial X} Q_{X1} = 0 \tag{2.18}$$

Substituting for Q_{X1} in equation (2.17), we have

$$\frac{\partial}{\partial X} \left[\left(\frac{\partial P}{\partial X}\right)_1 (h_1 J_1 - J_2) + C_1 (h_1 J_0 - J_1) + U_0 h_1 \right] = 0 \tag{2.19}$$

Substituting for C_1 from equation (2.10) in equation (2.19) and rearranging gives

$$\left(\frac{\partial^2 P}{\partial X^2}\right)_1 \left(\frac{J_1^2}{J_0} - J_2\right) = 0 \quad (2.20)$$

So we have $\left(\frac{\partial^2 P}{\partial X^2}\right)_1 = 0$ (2.21)

that is $\left(\frac{\partial P}{\partial X}\right)_1 = \text{Constant}$ (2.22)

Assuming that at the point where $X = L_1$, pressure reaches its maximum value P_m , we have

$$\left(\frac{\partial P}{\partial X}\right)_1 = \frac{P_m}{L_1} \quad (2.23)$$

Following the same procedure mentioned above, we have the following equations for the second section of the unit

$$Q_{X2} = \left(\frac{\partial P}{\partial X}\right)_2 (h_2 J'_1 - J'_2) + C'_1 (h_2 J'_0 - J'_1) + U_0 h_2 \quad (2.24)$$

$$J'_0 = \int_0^{h_2} \frac{1}{\mu(Y')} dY' \quad (2.25)$$

$$J'_1 = \int_0^{h_2} \frac{Y'}{\mu(Y')} dY' \quad (2.26)$$

$$J'_2 = \int_0^{h_2} \frac{Y'^2}{\mu(Y')} dY' \quad (2.27)$$

$$\left(\frac{\partial P}{\partial X}\right)_2 = - \frac{P_m}{L_2} \quad (2.28)$$

The continuity of flow gives

$$Q_{X1} = Q_{X2} \quad (2.29)$$

Substituting for Q_{X1} , Q_{X2} , $\left(\frac{\partial P}{\partial X}\right)_1$ and $\left(\frac{\partial P}{\partial X}\right)_2$ from equations (2.17), (2.24), (2.23) and (2.28) respectively in equation (2.29) and rearranging gives

$$P_m = \frac{U_0 L_1 L_2 (J_1 J'_0 - J'_1 J_0)}{-L_1 J_0 (J_1'^2 - J_2' J'_0) - L_2 J'_0 (J_1^2 - J_2 J_0)} \quad (2.30)$$

Axial stress in the wire

Substituting for $\frac{\partial u}{\partial Y}$ from equation (2.5) in equation (2.3) gives

$$\tau = \frac{\partial P}{\partial X} Y + C_1 \quad (2.31)$$

On the surface of the wire in the first section of the wire, where $Y = 0$, the shear stress is given by

$$\tau_X = C_1 = - \frac{U_0 + \frac{P_m}{L_1} J_1}{J_0} \quad (2.32)$$

This shear stress gives rise to drag forces in the wire and at a point X from the entry point within the unit in the first section, the axial stress developed in the wire is given by

$$\sigma(X) = \frac{4}{D_1} \int_0^X \tau_X dX \quad (2.33)$$

Integrating equation (2.33) gives

$$\sigma(X) = \frac{4X\tau_X}{D_1} \quad (2.34)$$

2.3.2 - Prediction of the Position of Yield of the Wire Inside the Unit

The axial distance, X_0 , from the entry point of the unit where yield occurs in the wire may be determined by the combined effects of the axial stress and the hydrodynamic pressure.

The pressure at point X is given by

$$P(X) = \frac{P_m}{L_1} X \quad (2.35)$$

The flow stress of the wire is assumed to be expressed as

$$\bar{Y} = Y_0 + A\epsilon^n$$

Where A and n are the strain hardening factor of the wire and the material constant respectively, $\epsilon = 2 \ln\left(\frac{D_1}{D}\right)$. Then the plastic yield will commence as soon as the yield criterion

$$P(X_0) + \sigma(X_0) = Y_0 \quad (2.36)$$

is satisfied

Substituting for $P(X_0)$ and $\sigma(X_0)$ from equations (2.34) and (2.35) respectively in equation (2.36) and rearranging gives

$$X_0 = \frac{Y_0}{\frac{P_m}{L_1} - \frac{4\tau_x}{D_1}} \quad (2.37)$$

Now J_0 , J_1 , J_2 , J'_0 , J'_1 and J'_2 are still unknown. They can be solved by application of the energy equation to the process of wire drawing.

Once plastic yield commences at point $X = X_0$, further permanent deformation will continue to take place in the wire as long as the yield criterion

$$P(X) + \sigma(X) > = \bar{Y} \quad (2.38)$$

is satisfied at any point within the first section, distance X from the yield starting point X_0 .

2.3.3 - Energy Equation Applied to the Process

Determination of J_0 , J_1 and J_2 in the first section of the unit

The Energy equation for the plasto-hydrodynamic process of the dieless wire drawing is given (Appendix 3) by

$$\frac{\partial^2 T}{\partial Y^2} = -\frac{\mu}{K} \left(\frac{\partial u}{\partial Y} \right)^2 \quad (2.39)$$

Where T is the temperature variation of the polymer melt from the reference temperature

K is the conductivity of the polymer melt

Here only the effect of the thermal energy generated by viscous "friction" in the drawing process is taken into consideration.

Rewriting equation (2.5)

$$\frac{\partial u}{\partial Y} = \frac{1}{\mu} \frac{\partial P}{\partial X} Y + \frac{C_1}{\mu} \quad (2.40)$$

where

$$C_1 = - \frac{U_0 + \frac{\partial P}{\partial X} J_1}{J_0}$$

To simplify mathematical processing, here we assume that $\frac{\partial P}{\partial X} = 0$

$$\text{hence} \quad \frac{\partial u}{\partial Y} = - \frac{U_0}{\mu J_0} \quad (2.41)$$

Substituting for $\frac{\partial u}{\partial Y}$ from equation (2.41) in equation (2.39) gives

$$\frac{\partial^2 T}{\partial Y^2} = - \frac{U_0^2}{K \mu J_0^2} \quad (2.42)$$

Substituting $\mu = \mu_0 e^{-aT}$ into equation (2.42), we have

$$\frac{\partial^2 T}{\partial Y^2} = - \frac{U_0^2}{K \mu_0 J_0^2} e^{aT} \quad (2.43)$$

Multiplying both sides by $\frac{\partial T}{\partial Y}$ and rewriting, we have

$$\frac{\partial}{\partial Y} \left[\frac{1}{2} \left(\frac{\partial T}{\partial Y} \right)^2 \right] = - \frac{U_0^2}{K \mu_0 J_0^2 a} \frac{\partial}{\partial Y} e^{aT}$$

Integrating both sides with respect to Y gives

$$\left(\frac{\partial T}{\partial Y} \right)^2 = - \frac{2 U_0^2 e^{aT}}{K \mu_0 J_0^2 a} + C_3 \quad (2.44)$$

Now integrating equation (2.42) with respect to Y between 0 and h_1 gives

$$\begin{aligned}\frac{\partial T}{\partial Y}\bigg|_{Y=h_1} - \frac{\partial T}{\partial Y}\bigg|_{Y=0} &= - \frac{U_0^2}{KJ_0^2} \int_0^{h_1} \frac{dY}{\mu(Y)} \\ &= - \frac{U_0^2}{KJ_0}\end{aligned}\tag{2.45}$$

By symmetry

$$\frac{\partial T}{\partial Y}\bigg|_{Y=0} = - \frac{\partial T}{\partial Y}\bigg|_{Y=h_1}\tag{2.46}$$

Hence from equations (2.45) and (2.46), we have

$$\frac{\partial T}{\partial Y}\bigg|_{Y=h_1} = - \frac{U_0^2}{2KJ_0}\tag{2.47}$$

Thus

$$\left(\frac{\partial T}{\partial Y}\right)^2_{Y=h_1} = \frac{U_0^4}{4K^2 J_0^2}\tag{2.48}$$

Applying the boundary condition that $T = 0$ at $Y = h_1$ to equation (2.44), we have

$$\left(\frac{\partial T}{\partial Y}\right)^2_{Y=h_1} = - \frac{2U_0^2}{K\mu_0 J_0^2 a} + C_3\tag{2.49}$$

Equating equations (2.48) and (2.49) gives

$$C_3 = \frac{U_0^2}{KJ_0^2} \left[\frac{U_0^2}{4K} + \frac{2}{a\mu_0} \right]$$

Substituting for C_3 in equation (2.44) gives

$$\left(\frac{\partial T}{\partial Y}\right)^2 = \frac{2U_0^2}{aK\mu_0 J_0^2} \left[\left(1 + \frac{a\mu_0 U_0^2}{8K}\right) - e^{aT} \right]\tag{2.50}$$

Let
$$A_1 = \frac{2U_0^2}{aK\mu_0 J_0^2} \quad (2.51)$$

$$B = 1 + \frac{a\mu_0 U_0^2}{8K} \quad (2.52)$$

Equation (2.50) becomes

$$\left(\frac{\partial T}{\partial Y}\right)^2 = A_1 (B - e^{aT}) \quad (2.53)$$

Because $T = T(Y)$ only, rearranging equation (2.53) gives

$$\frac{dT}{dY} = \sqrt{A_1 (B - e^{aT})} \quad 0 < Y < h_1/2 \quad (2.54)$$

and
$$\frac{dT}{dY} = - \sqrt{A_1 (B - e^{aT})} \quad h_1/2 < Y < h_1 \quad (2.55)$$

By symmetry, at point where $Y = h_1/2$ and $\frac{dT}{dY} = 0$, T reaches its maximum value T_m . From equation (2.53), we have

$$B - e^{aT_m} = 0$$

That is
$$T_m = \frac{1}{a} \ln B$$

Rearranging equation (2.54) gives

$$\frac{dT}{\sqrt{B - e^{aT}}} = \sqrt{A_1} dY \quad (2.56)$$

Now integrating equation (2.56) both sides gives

$$\frac{1}{a\sqrt{B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| = \sqrt{A_1} Y + C_4 \quad (2.57)$$

Applying the boundary condition that $T = T_m$ at $Y = h_1/2$ to equation (2.57) gives

$$C_4 = - \frac{h_1}{2} \sqrt{A_1} \quad (2.58)$$

Applying the boundary condition that $T = 0$ at $Y = 0$ to equation (2.57) gives

$$C_4 = \frac{1}{A\sqrt{B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \quad (2.59)$$

Equating equation (2.58) and equation (2.59), we have

$$\frac{h_1}{2} = - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \quad (2.60)$$

Substituting for A_1 from equation (2.51) in equation (2.60) and rearranging gives

$$J_0 = \frac{\frac{\sqrt{BU_0^2 h_1^2 a}}{2K\mu_0}}{\ln \left| \frac{\sqrt{B-1} + \sqrt{B}}{\sqrt{B-1} - \sqrt{B}} \right|} \quad (2.61)$$

Substituting for C_4 from equation (2.59) in equation (2.57) and rearranging gives

$$Y = \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \quad (2.62)$$

for $0 < Y < h_1/2$

Rearranging equation (2.55) gives

$$\frac{dT}{\sqrt{B - e^{aT}}} = - \sqrt{A_1} dY \quad (2.63)$$

Integrating both sides gives

$$\frac{1}{a\sqrt{B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| = - \sqrt{A_1} Y + C_5 \quad (2.64)$$

Applying the boundary condition that $T = 0$ at $Y = h_1$ to equation (2.64), we have

$$C_5 = \sqrt{A_1} h_1 + \frac{1}{a\sqrt{B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \quad (2.65)$$

Substituting for C_5 in equation (2.64) gives

$$Y = \frac{-1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| + \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| + h_1 \quad (2.66)$$

Substituting for h_1 from equation (2.60) in equation (2.66) gives

$$Y = - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \quad (2.67)$$

for $h_1/2 < Y < h_1$

Rewriting equation (2.9) gives

$$J_1 = \int_0^{h_1} \frac{Y}{\mu} dY = \int_0^{\frac{h_1}{2}} \frac{Y}{\mu} dY + \int_{\frac{h_1}{2}}^{h_1} \frac{Y}{\mu} dY \quad (2.68)$$

Substituting for $\mu = \mu_0 e^{-aT}$, for dY from equation (2.56) and Y from equation (2.62) in the first integration term of equation (2.68); and for dY from equation (2.63) and Y from equation (2.67) in the second integration term of equation (2.68), we have

$$\begin{aligned} J_1 &= \int_0^{T_m} \frac{e^{aT}}{\sqrt{A_1}(B - e^{aT}) \mu_0} \left[\frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \right] dT \\ &+ \int_{T_m}^0 \frac{-e^{aT}}{\sqrt{A_1}(B - e^{aT}) \mu_0} \left[\frac{-1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B - e^{aT}} - \sqrt{B}}{\sqrt{B - e^{aT}} + \sqrt{B}} \right| - \frac{1}{a\sqrt{A_1 B}} \ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \right] dT \\ &= \frac{4\sqrt{B-1}}{a^2 \mu_0 A_1 \sqrt{B}} \ln \left| \frac{\sqrt{B-1} + \sqrt{B}}{\sqrt{B-1} - \sqrt{B}} \right| \end{aligned} \quad (2.69)$$

Rewriting equation (2.14) gives

$$J_2 = \int_0^{h_1} \frac{Y^2}{\mu} dY = \int_0^{\frac{h_1}{2}} \frac{Y^2}{\mu} dY + \int_{\frac{h_1}{2}}^{h_1} \frac{Y^2}{\mu} dY \quad (2.70)$$

Following the same procedure as above, we have

$$J_2 = 2 \int_0^{T_m} \frac{e^{aT}}{\sqrt{A_1(B-e^{aT})} \mu_0 a^2 A_1 B} \left[\ln \left| \frac{\sqrt{B-e^{aT}} - \sqrt{B}}{\sqrt{B-e^{aT}} + \sqrt{B}} \right| \right]^2 dT$$

$$+ \frac{4\sqrt{B-1}}{a^2 A_1 B \sqrt{A_1} \mu_0} \left[\ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \right]^2 \quad (2.71)$$

The first term on the right side of equation (2.71) could be calculated by using a numerical integration method.

Determination of J'_0 , J'_1 and J'_2 in the second section of the unit

Now similarly, for the second section of the unit, we have

$$J'_0 = \frac{\sqrt{\frac{BU_0^2 h^2 a}{2K\mu_0}}}{\ln \left| \frac{\sqrt{B-1} + \sqrt{B}}{\sqrt{B-1} - \sqrt{B}} \right|} \quad (2.72)$$

$$A_2 = \frac{2U_0^2}{aK\mu_0 J_0'^2} \quad (2.73)$$

$$J'_1 = \frac{4\sqrt{B-1}}{a^2 \mu_0 A_2 \sqrt{B}} \ln \left| \frac{\sqrt{B-1} + \sqrt{B}}{\sqrt{B-1} - \sqrt{B}} \right| \quad (2.74)$$

$$J_2' = 2 \int_0^{T_m} \frac{e^{aT}}{\sqrt{A_2(B-e^{aT})} \mu_0 a^2 A_2 B} \left[\ln \left| \frac{\sqrt{B-e^{aT}} - \sqrt{B}}{\sqrt{B-e^{aT}} + \sqrt{B}} \right| \right]^2 dT$$

$$+ \frac{4\sqrt{B-1}}{a^3 A_2 B \sqrt{A_2} \mu_0} \left[\ln \left| \frac{\sqrt{B-1} - \sqrt{B}}{\sqrt{B-1} + \sqrt{B}} \right| \right]^2 \quad (2.75)$$

2.3.4 - Prediction of Deformation Profile in the Deformation Zone

The reduced Reynolds equation

It is assumed that deformation takes place from the point of yield where $X = X_0$ and ceases at the step. In the deformation zone, rewriting equation (2.19) with gap h , we have

$$\frac{\partial}{\partial X} \left[\frac{\partial P}{\partial X} (h J_1 - J_2) + C_1 (h J_0 - J_1) + U_0 h \right] = 0 \quad (2.76)$$

where

$$J_0 = \int_0^h \frac{dY}{\mu(Y)}$$

$$J_1 = \int_0^h \frac{Y}{\mu(Y)} dY$$

$$J_2 = \int_0^h \frac{Y^2}{\mu(Y)} dY$$

Substituting for C_1 from equation (2.10) in equation (2.76) and rearranging gives

$$\frac{\partial}{\partial X} \left[\left(\frac{J_1^2 - J_2 J_0}{J_0} \right) \frac{\partial P}{\partial X} \right] = - U_0 \frac{\partial}{\partial X} \left(\frac{J_1}{J_0} \right) \quad (2.77)$$

Let $Z = Y/h$, then

$$J_0 = \int_0^h \frac{dY}{\mu(Y)} = \int_0^1 \frac{h}{\mu(Z)} dZ = h I_0 \quad (2.78)$$

where

$$I_0 = \int_0^1 \frac{dz}{\mu(z)} \quad (2.79)$$

Following the same procedure, we have

$$J_1 = \int_0^h \frac{y}{\mu(y)} dy = h^2 I_1 \quad (2.80)$$

$$J_2 = \int_0^h \frac{y^2}{\mu(y)} dy = h^3 I_2 \quad (2.81)$$

where

$$I_1 = \int_0^1 \frac{z}{\mu(z)} dz \quad (2.82)$$

$$I_2 = \int_0^1 \frac{z^2}{\mu(z)} dz \quad (2.83)$$

Substituting for J_0 , J_1 and J_2 in equation (2.77) gives

$$\frac{\partial}{\partial X} \left[6h^3 \frac{(I_1^2 - I_2 I_0)}{-I_1} \frac{\partial P}{\partial X} \right] = 6U_0 \frac{\partial h}{\partial X} \quad (2.84)$$

Then define

$$\mu^* = \frac{6(I_1^2 - I_2 I_0)}{-I_1} \quad (2.85)$$

Then, equation (2.84) becomes

$$\frac{\partial}{\partial X} \left[\mu^* h^3 \frac{\partial P}{\partial X} \right] = 6U_0 \frac{\partial h}{\partial X} \quad (2.86)$$

which is the reduced Reynolds equation with variable viscosity μ^* .

After deformation takes place, the gap between the surface of the wire and the orifice within the unit will no longer hold constant. Since $I_n = I_n(h)$, ($n=0,1,2$) and $h = h(X)$, we have $\mu^* = \mu^*(h) = \mu^*(X)$. Now it is assumed that in deformation zone, the values of J_n and I_n are the

same as those before deformation occurs. With this assumption it follows that μ^* will have a constant value at a given drawing velocity before and after deformation occurs and thus its value can be easily calculated from equation (2.85). When deformation is within a limited range, this assumption can be accepted.

Determination of pressure in the deformation zone

With the assumption that μ^* is constant along the length of the unit at a given drawing velocity, rewriting equation (2.86), we have

$$\frac{\partial}{\partial X}(h^3 \frac{\partial P}{\partial X}) = 6U_0 \mu^* \frac{\partial h}{\partial X} \quad (2.87)$$

where X is the distance from the point of yield, h is the gap at any point X in the deformation zone

$$h = h_1 + bX^2 \quad (2.88)$$

It is assumed that deformation takes place from the point of yield and ceases at the step, where $X = L_1 - X_0$

From equation (2.88)

$$\frac{\partial h}{\partial X} = 2bX \quad (2.89)$$

Substituting for $\frac{\partial h}{\partial X}$ in equation (2.87) and integrating, we have

$$h^3 \frac{\partial P}{\partial X} = 6\mu^* U_0 bX^2 + C_6 \quad (2.90)$$

Applying the boundary condition that $(\frac{\partial P}{\partial X})_1 = \frac{P_m}{L_1}$, at $X=0$, where $h = h_1$, the constant C_6 is given by

$$C_6 = \frac{h_1^3 P_m}{L_1} \quad (2.91)$$

Substituting for h and C_6 in equation (2.90), we have

$$\frac{\partial P}{\partial X} = 6\mu^* U_0 \frac{bX^2}{(h_1 + bX^2)^3} + \frac{P_m}{L_1} \frac{h_1^3}{(h_1 + bX^2)^3} \quad (2.92)$$

Let $m^2 = \frac{h_1}{b}$

Integrating equation (2.92) gives

$$P = 6\mu^*U_0 \left[\frac{\tan^{-1} \frac{X}{m}}{8m^3b^2} + \frac{X^3 - m^2X}{8m^2b^2(m^2 + X^2)^2} \right] + \frac{P_m h_1^3}{L_1 b^3} \left[\frac{3\tan^{-1} \frac{X}{m}}{8m^3} + \frac{5m^2X + 3X^3}{8m^4(m^2 + X^2)^2} \right] + C_7 \quad (2.93)$$

Applying the boundary condition that at $X = 0$, where plastic deformation starts, $P = \frac{P_m X_0}{L_1}$, we have

$$C_7 = \frac{P_m X_0}{L_1} \quad (2.94)$$

So equation (2.93) becomes

$$P = 6\mu^*U_0 \left[\frac{\tan^{-1} \frac{X}{m}}{8m^3b^2} + \frac{X^3 - m^2X}{8m^2b^2(m^2 + X^2)^2} \right] + \frac{P_m}{L_1} \left[X_0 + \frac{3m \tan^{-1} \frac{X}{m}}{8} + \frac{5m^4X + 3m^2X^3}{8(m^2 + X^2)^2} \right] \quad (2.95)$$

which gives the pressure distribution along the length $(L_1 - X_0)$ within the DRU and up to the step.

Determination of axial stress in the deformation zone

In the deformation zone, the expression of $\frac{\partial u}{\partial Y}$ may be given by equation (2.5) by simply replacing μ^* for μ , thus

$$\frac{\partial u}{\partial Y} = \frac{1}{\mu^*} \frac{\partial P}{\partial X} Y + \frac{C_8}{\mu^*} \quad (2.96)$$

Integrating both sides of equation (2.96) with respect to Y gives

$$u = \frac{1}{\mu^*} \frac{\partial P}{\partial X} \frac{Y^2}{2} + \frac{C_8}{\mu^*} Y + C_9 \quad (2.97)$$

Applying the boundary condition that $u = U_0$, at $Y = 0$ and $u = 0$ at $Y = h$, we have

$$C_8 = -\frac{\partial P}{\partial X} \frac{h}{2} - \frac{U_0 \mu^*}{h}$$

$$C_9 = U_0$$

Substituting for C_8 into equation (2.96) gives

$$\frac{\partial u}{\partial Y} = \frac{1}{\mu^*} \frac{\partial P}{\partial X} \left(Y - \frac{h}{2} \right) - \frac{U_0}{h} \quad (2.98)$$

The shear stress on the deformed wire surface may be expressed by

$$\tau_c = \mu^* \left. \frac{\partial u}{\partial Y} \right|_{Y=0} \quad (2.99)$$

The combination of equation (2.98) and equation (2.99) gives

$$\tau_c = -\frac{h}{2} \left(\frac{\partial P}{\partial X} \right) - \frac{\mu^* U_0}{h} \quad (2.100)$$

Now substituting for $\frac{\partial P}{\partial X}$ from equation (2.92), we have

$$\tau_c = -\frac{\mu^* U_0 (m^2 + 4X^2)}{b(m^2 + X^2)^2} - \frac{P_m h_1 m^4}{2L_1 (m^2 + X^2)^2} \quad (2.101)$$

The axial force equilibrium condition for a small element of the wire shown in Fig. 2.1b gives

$$d\sigma_X = -2 \frac{dD}{D} (Y + \tau_c \cot \alpha) \quad (2.102)$$

But $D = D_1 - 2bX^2$, hence $dD = -4bX dX$, $\tan \alpha = \frac{dD}{2dX} = -2bX$ and $\cot \alpha = -\frac{1}{2bX}$. Substituting for dD , $\cot \alpha$ and τ_c in equation (2.102), we obtain

$$\begin{aligned} d\sigma = & \frac{8bXYdX}{(D_1 - 2bX^2)} + \frac{4\mu^* U_0 (m^2 + 4X^2)dX}{b(D_1 - 2bX^2)(m^2 + X^2)^2} \\ & + \frac{2P_m h_1 m^4 dX}{L_1 (m^2 + X^2)^2 (D_1 - 2bX^2)} \end{aligned} \quad (2.103)$$

As mentioned before the stress-strain relationship of the wire material has been shown to take the form

$$\bar{Y} = Y_0 + A\epsilon^n$$

where

$$\epsilon = 2 \ln\left(\frac{D_1}{D_1 - 2bX^2}\right)$$

Therefore

$$\bar{Y} = Y_0 + A \left[2 \ln \frac{D_1}{D_1 - 2bX^2} \right]^n \quad (2.104)$$

Substituting for \bar{Y} into equation (2.103) gives

$$\begin{aligned} d\sigma_X = & \frac{8bXY_0 dX}{D_1 - 2bX^2} + \frac{8bXA \left[2 \ln\left(\frac{D_1}{D_1 - 2bX^2}\right) \right]^2 dX}{D_1 - 2bX^2} \\ & + \frac{4\mu^* U_0 (m^2 + 4X^2) dX}{b(D_1 - 2bX^2)(m^2 + X^2)^2} + \frac{2P_m h_1 m^4 dX}{L_1 (m^2 + X^2)^2 (D_1 - 2bX^2)} \end{aligned} \quad (2.105)$$

Integrating equation (2.105), the expression for the axial stress is obtained as

$$\begin{aligned} \sigma_X = & -2Y_0 \ln(D_1 - 2bX^2) - \frac{2A}{n+1} \left[2 \ln(D_1 - 2bX^2) \right]^{n+1} \\ & - \frac{4\mu^* U_0}{b} \left[\frac{4b(2D_1 + m^2 b)}{\sqrt{2bD_1}(D_1 + 2bm^2)^2} \ln\left(\frac{\sqrt{D_1} + X\sqrt{2b}}{\sqrt{D_1} + 2bX^2}\right) \right. \\ & + \frac{5D_1 - 2bm^2}{2m(D_1 + 2bm^2)^2} \tan^{-1} \frac{X}{m} - \frac{3X}{2(D_1 + 2bm^2)(m^2 + X^2)} \Big] \\ & + \frac{2P_m h_1}{L_1} \left[\frac{m^2 X}{2(D_1 + 2bm^2)(m^2 + X^2)} + \frac{m(D_1 + 6bm^2)}{2(D_1 + 2bm^2)^2} \tan^{-1} \frac{X}{m} \right. \\ & + \frac{4m^2 b^2}{\sqrt{2bD_1}(D_1 + 2bm^2)^2} \ln\left(\frac{\sqrt{D_1} + X\sqrt{2b}}{\sqrt{D_1} - X\sqrt{2b}}\right) \Big] + C_{10} \end{aligned} \quad (2.106)$$

Applying the boundary condition, $\sigma_X = \frac{4X_0 \tau_x}{D_1}$ at $X = 0$ into equation (2.106), the constant C_{10} is obtained as

$$C_{10} = \frac{4X_0 \tau_x}{D_1} + 2Y_0 \ln D_1 + \frac{2A}{n+1} [2 \ln D_1]^{n+1}$$

which upon substituting in equation (2.106) yields

$$\begin{aligned} \sigma_X = & 2Y_0 \ln \frac{D_1}{D_1 - 2bX^2} + \frac{4\mu^* U_0}{b} \left[\frac{(2D_1 + bm^2)\sqrt{2b}}{\sqrt{D_1}(D_1 + 2bm^2)^2} \ln \frac{\sqrt{D_1} + X\sqrt{2b}}{\sqrt{D_1} - X\sqrt{2b}} \right. \\ & + \frac{5D_1 - 2bm^2}{2m(D_1 + 2bm^2)^2} \tan^{-1} \frac{X}{m} - \frac{3X}{2(D_1 + 2bm^2)(m^2 + X^2)} \left. \right] \\ & + \frac{2P_m h_1}{L_1} \left[\frac{m^2 X}{2(D_1 + 2bm^2)(m^2 + X^2)} + \frac{m(D_1 + 6bm^2)}{2(D_1 + 2bm^2)^2} \tan^{-1} \frac{X}{m} \right. \\ & + \frac{4m^4 b^2}{\sqrt{2bD_1}(D_1 + 2bm^2)^2} \ln \frac{\sqrt{D_1} + X\sqrt{2b}}{\sqrt{D_1} - X\sqrt{2b}} \left. \right] \\ & + \frac{A}{n+1} \left[2 \ln \frac{D_1}{D_1 - 2bX^2} \right]^{n+1} + \frac{4X_0}{D_1} \tau_x \end{aligned} \quad (2.107)$$

Deformation Profile

Applying the yield criterion again

$$P + \sigma_X = Y_0 + A \left[2 \ln \frac{D_1}{D_1 - 2bX^2} \right]^n \quad (2.108)$$

Equation (2.108), when substitutions are made for P and σ_X from equations (2.95) and (2.107) respectively, may be iterated to establish the value of b for a given drawing velocity and DRU geometry. Once the value of b is established, the deformation profile is obtained and the reduction in area at any point for $X_0 < X < L_1$ is given by

$$PRA = \left[1 - \left(\frac{D_1 - 2bX^2}{D_1} \right)^2 \right] * 100$$

where the PRA is the percentage reduction in area. It is assumed that no further deformation takes place after the step within the DRU and hence the maximum reduction in area is given by

$$PRA = \left\{ 1 - \left[\frac{D_1 - 2b(L_1 - X_0)^2}{D_1} \right]^2 \right\} * 100$$

A computer program was written to solve the relevant equations, the flowchart and listing of which are given in Appendix 4.

2.4 - Results and Discussion

Theoretical results were calculated on the basis of the equations derived in the previous analysis for copper wire. The standard values of the parameters were assumed to be as follows [7]:

Viscosity $\mu_0 = 110 \text{ Ns/m}^2$

Length of the first section $L_1 = 50 \text{ mm}$

Length of the second section $L_1 = 20 \text{ mm}$

Initial gap $h_1 = 0.15 \text{ mm}$ or $h_1 = 0.2 \text{ mm}$

Final gap $h_2 = 0.1 \text{ mm}$ or $h_2 = 0.05 \text{ mm}$

Original diameter of the wire $D_1 = 0.46 \text{ mm}$ or $D_1 = 1.6 \text{ mm}$

Initial yield stress of the wire $Y_0 = 50 \text{ MN/m}^2$

Strain hardening factor of the wire $A = 440 \text{ MN/m}^2$

Material constant $n = 0.52$

Viscosity temperature dependency constant $a = 0.175 \text{ K}^{-1}$

Thermal conductivity $K = 0.13 \text{ W/mK}$

Theoretical percentage reduction in area

Figs. 2.2 to 2.4 show the variations of the percentage reduction in area versus drawing speed predicted theoretically. For comparison purposes, some experimental results [7] are also shown in Figs. 2.2 to 2.4.

In Fig. 2.3 experimental results were obtained at the temperature of 130°C , so the equivalent theoretical results were produced by changing the initial viscosity of the polymer melt to 85 Ns/m^2 due to the effect of the reference temperature on the initial viscosity. In Figs. 2.2 and 2.3, the results predicted theoretically show very close agreement with those obtained experimentally.

In Fig. 2.4, both theoretical and experimental results were produced with the parameters of the gap ratio $R_h = 4$, final gap $h_2 = 0.05\text{ mm}$ and the initial diameter of the wire $D_1 = 1.6\text{ mm}$. The discrepancies between the theoretical and experimental results become apparent. Theoretical results appear to estimate lower percentage reduction in area at lower speeds and higher percentage reduction in area at higher speeds compared to those obtained experimentally.

Theoretical effect of changing the parameters representing the polymer melt rheology are shown in Fig. 2.5 and Fig. 2.6. The theoretical effects of changing thermal conductivity K is shown in Fig. 2.5, where the percentage reduction in area is shown to increase as K is increased. Fig. 2.6 shows the effect of the viscosity temperature dependency constant " a " on the predicted percentage reduction in area where the percentage reduction in area is shown to increase as " a " is decreased.

Theoretical Pressure

The pressure distributions within the unit were predicted theoretically for drawing speeds of 0.5 ms^{-1} and 1 ms^{-1} and those are shown in Figs. 2.7 and 2.8 respectively. Figs. 2.7 and 2.8 also show the pressure distributions within the unit obtained experimentally [7]. In the experiment, the maximum pressure of about 87.5 MN/m^2 occurred at drawing speed of 1 ms^{-1} , and about 77 MN/m^2 at drawing speed of 0.5 ms^{-1} , whilst the maximum pressure of about 109 MN/m^2 was predicted to occur at a speed of 1 ms^{-1} and 93 MN/m^2 at a speed of 0.5 ms^{-1} . It was clearly shown that the magnitudes of the maximum pressure predicted theoretically were close to those obtained experimentally.

The pressure values predicted theoretically versus drawing speed at the point where the distance from the entry point was 45 mm within the unit, and those obtained experimentally [7] at the same position, both for the maximum reduction in area of about 7 percent are shown in Fig. 2.9. In the experiment, the pressure of about 62.5 MN/m^2 occurred at a speed of 0.3 ms^{-1} for a reduction in area of about 7 percent, whilst the pressure of about 113 MN/m^2 was predicted to occur at a speed of 1.5 ms^{-1} for the same percentage reduction in area. Theoretical results tended to under-estimate the experimental results at slower drawing speeds and over-estimate the measured results at higher speeds.

Fig. 2.7 Pressure Distributions Within the DRU

Fig. 2.8 Pressure Distributions Within the DRU

Fig. 2.9 Pressure Variations Versus Drawing Speed

Theoretical Drawing Loads

Drawing loads predicted theoretically and those obtained experimentally, both for the maximum reduction in area of about 7 percent, are shown in Fig. 2.10. In the experiment, the maximum drawing load of about 120 N occurred at the speed of 0.3 ms^{-1} for the reduction in area of about 7 percent, whilst the maximum drawing load of about 100 N was predicted to occur at the speed of 1.5 ms^{-1} for the same reduction in area. Theoretical results appeared to have lower values through all the range of the drawing speeds compared with the experimental results.

Fig. 2.10 Drawing Load Variations Versus Drawing Speed

Discussion

The present analysis enabled the prediction of the percentage reduction in area, the pressure of the polymer melt within the unit and the axial stress in the wire. The theoretical investigation of the effect of several factors (for example, drawing speed and the temperature of the polymer melt) on the percentage reduction in area, enabled a basic control strategy to be established. This will be discussed in Chapter 3.

The Energy equation used in analysis takes the form:

$$\frac{\partial^2 T}{\partial Y^2} = -\frac{\mu}{K} \left(\frac{\partial u}{\partial Y} \right)^2$$

This simplified equation was used to predict the increase in the temperature of the polymer melt within the unit. During the wire drawing process energy is dissipated in two ways: through the action of viscous "friction" and through the plastic deformation of the wire. Both of these sources liberate heat which changes the melt temperature. However, the amount of heat generated from the deformation of the wire was not taken into consideration in the analysis. The viscosity of the polymer melt is known to be sensitive to temperature, therefore this may have introduced some discrepancy between the theoretical and practical results.

The apparent viscosity as a function of the melt temperature in the analysis is given by $\mu = \mu_0 e^{-aT}$. It is derived from Fig. 2.11. Note that the data indicating the viscosity dependance of temperature in Fig. 2.11 are at constant shear stress and pressure. It is known that usually for shear thinning polymer melt the increase in shear stress causes the decrease in apparent viscosity. Fig. 2.12 shows the behaviour of the shear thinning polymer. Fig. 2.13 presents the apparent viscosity of the polymer melt as a function of pressure. It must be remembered

that the shear stress and the pressure applied to the polymer melt within the unit during the wire drawing process were very high. However these effects were not incorporated in analysis and hence this might have contributed to the discrepancy in the results.

The value of the thermal conductivity K , used in the analysis, was 0.13 W/mK. This value was selected as being within the range normally encountered [13].

From Fig. 2.11 the magnitude of the viscosity temperature dependency constant " a " was estimated to be between 0.02 and 0.1 K^{-1} . However, in the analysis " a " was taken to 0.175 K^{-1} in order to have reasonable results, hence the value of " a " chosen for analysis was only an approximation.

The predicted results of the percentage reduction in area showed two zones:

- 1) At slower speeds, the percentage reduction in area increased as the drawing speed was increased and reached its maximum value.
- 2) Then, the percentage reduction in area reduced slowly as the drawing speed was increased further.

The drawing speed was found to have the most dramatic effect on the percentage reduction in area. Fig. 2.14 shows the predicted values of the temperature change, percentage reduction in area, viscosity, maximum pressure and axial stress versus drawing speeds. As might have been expected, an increase in drawing speed increased the temperature of the polymer melt within the unit which caused a decrease in viscosity of the polymer melt, hence a percentage reduction in area, and decreases in the maximum pressure and axial stress.

The effects of other variables were also examined theoretically in order to investigate their influences on the predicted results. An increase in initial viscosity increased the percentage reduction in

area. Increasing the thermal conductivity also had the same effect. A reduction in viscosity temperature dependency constant "a" increased the percentage reduction in area. An increase in the initial temperature of the polymer melt was also expected to decrease the percentage reduction in area.

A very good agreement appeared to exist between the theoretical and experimental results as shown in Figs. 2.2 and 2.3. However differences were observed between the theoretical and experimental results in Figs. 2.4, 2.9 and 2.10, where the geometry of the dieless reduction unit and the initial diameter of the wire differed from those in Figs. 2.2 and 2.3. This suggested that the analysis did not fully represent the actual drawing process and certain additional factors, as mentioned before, should be incorporated in the analysis in order to improve the theoretical results.

3.8 - Results and Discussion

3.1 - Introduction

From the previous theoretical analysis, it can be seen that during the wire drawing process, the reduction in area of the wire is affected by several factors; the significant ones are the drawing speed, the performance of the polymer used as pressure medium, the temperature of the polymer melt and the configuration of the DRU. The control of the process is primarily required for product quality, so methods of controlling the wire drawing process should be looked at in order to produce wires of desired qualities in terms of consistency in the diameter over a long length, or uniform change in area with a desired rate for a given length.

To further investigate the drawing process, an extensive experimental program was conducted, in which parameters such as drawing speed, the temperature of the polymer melt and polymers were varied, and a considerable amount of data was obtained. Some of the results are shown in Fig. 3.1 to Fig. 3.7.

From both theoretical and experimental results, the drawing speed is found to have the most dramatic effect on the reduction in area of the wire. The percentage reduction in area (PRA) versus drawing speed shows two zones: at slower drawing speed, the PRA increases as the drawing speed is increased, and then it reaches its maximum value. After that, the PRA reduces as the drawing speed is increased further. Compared with the second zone, the PRA curve in the first zone has better linearity and the full range of the PRA is spanned within a limited speed extent. So the design of the control system was based on the first zone.

The effect of the temperature on the viscosity of the polymer melt was included in the analysis by varying the initial viscosity. It was assumed that varying the initial viscosity had the same effect as the

change in temperature (see Fig. 2.2 to Fig. 2.3). Both theoretical and experimental results showed that the overall percentage reduction in area was affected greatly by the temperature of the polymer melt. Experiments also showed that it took about 70-80 minutes for the temperature to reach a uniform distribution within the melt chamber after a change in set temperature. Uniform temperature distribution was of great importance for a steady wire drawing process. The temperature could be a manipulated variable to control the PRA, but in consideration of the time needed for temperature to reach a uniform distribution, the control strategy was designed to keep the temperature constant during the whole drawing period. Instead, the drawing speed was regulated to produce the desired products. For each polymer, optimum drawing speed and temperature could be found at which the deformation of the wire reached its maximum value. It is often the case that the maximum PRA is desired for one pass during the drawing process.

Three polymers having different densities and viscosities were selected as pressure media. They were polymer WVG 23, Nylon 6 and ELVAX 650. With ELVAX 650 at 150°C the PRA curve was almost linear from a reduction in area of 4 percent at speed of 0.03 ms⁻¹ to a reduction in area of 21 percent at speed of 1.04 ms⁻¹, as shown in Fig. 3.6. Polymer WVG 23 at 110°C and polymer Nylon 6 at 260°C also showed good performance (see Fig. 3.1 and Fig. 3.3) in terms of wide range of PRA in the first zone. These results were employed in producing samples.

Fig. 3.4 Percentage Reduction in Area Versus Drawing Speed

Fig. 3.5 Percentage Reduction in Area Versus Drawing Speed

Fig. 3.6 Percentage Reduction in Area Versus Drawing Speed

Fig. 3.7 Percentage Reduction in Area Versus Drawing Speed

In practice, a single loop control system, as shown in Fig. 3.8 can be used to control the PRA of the wire, i.e., the diameter of the wire.

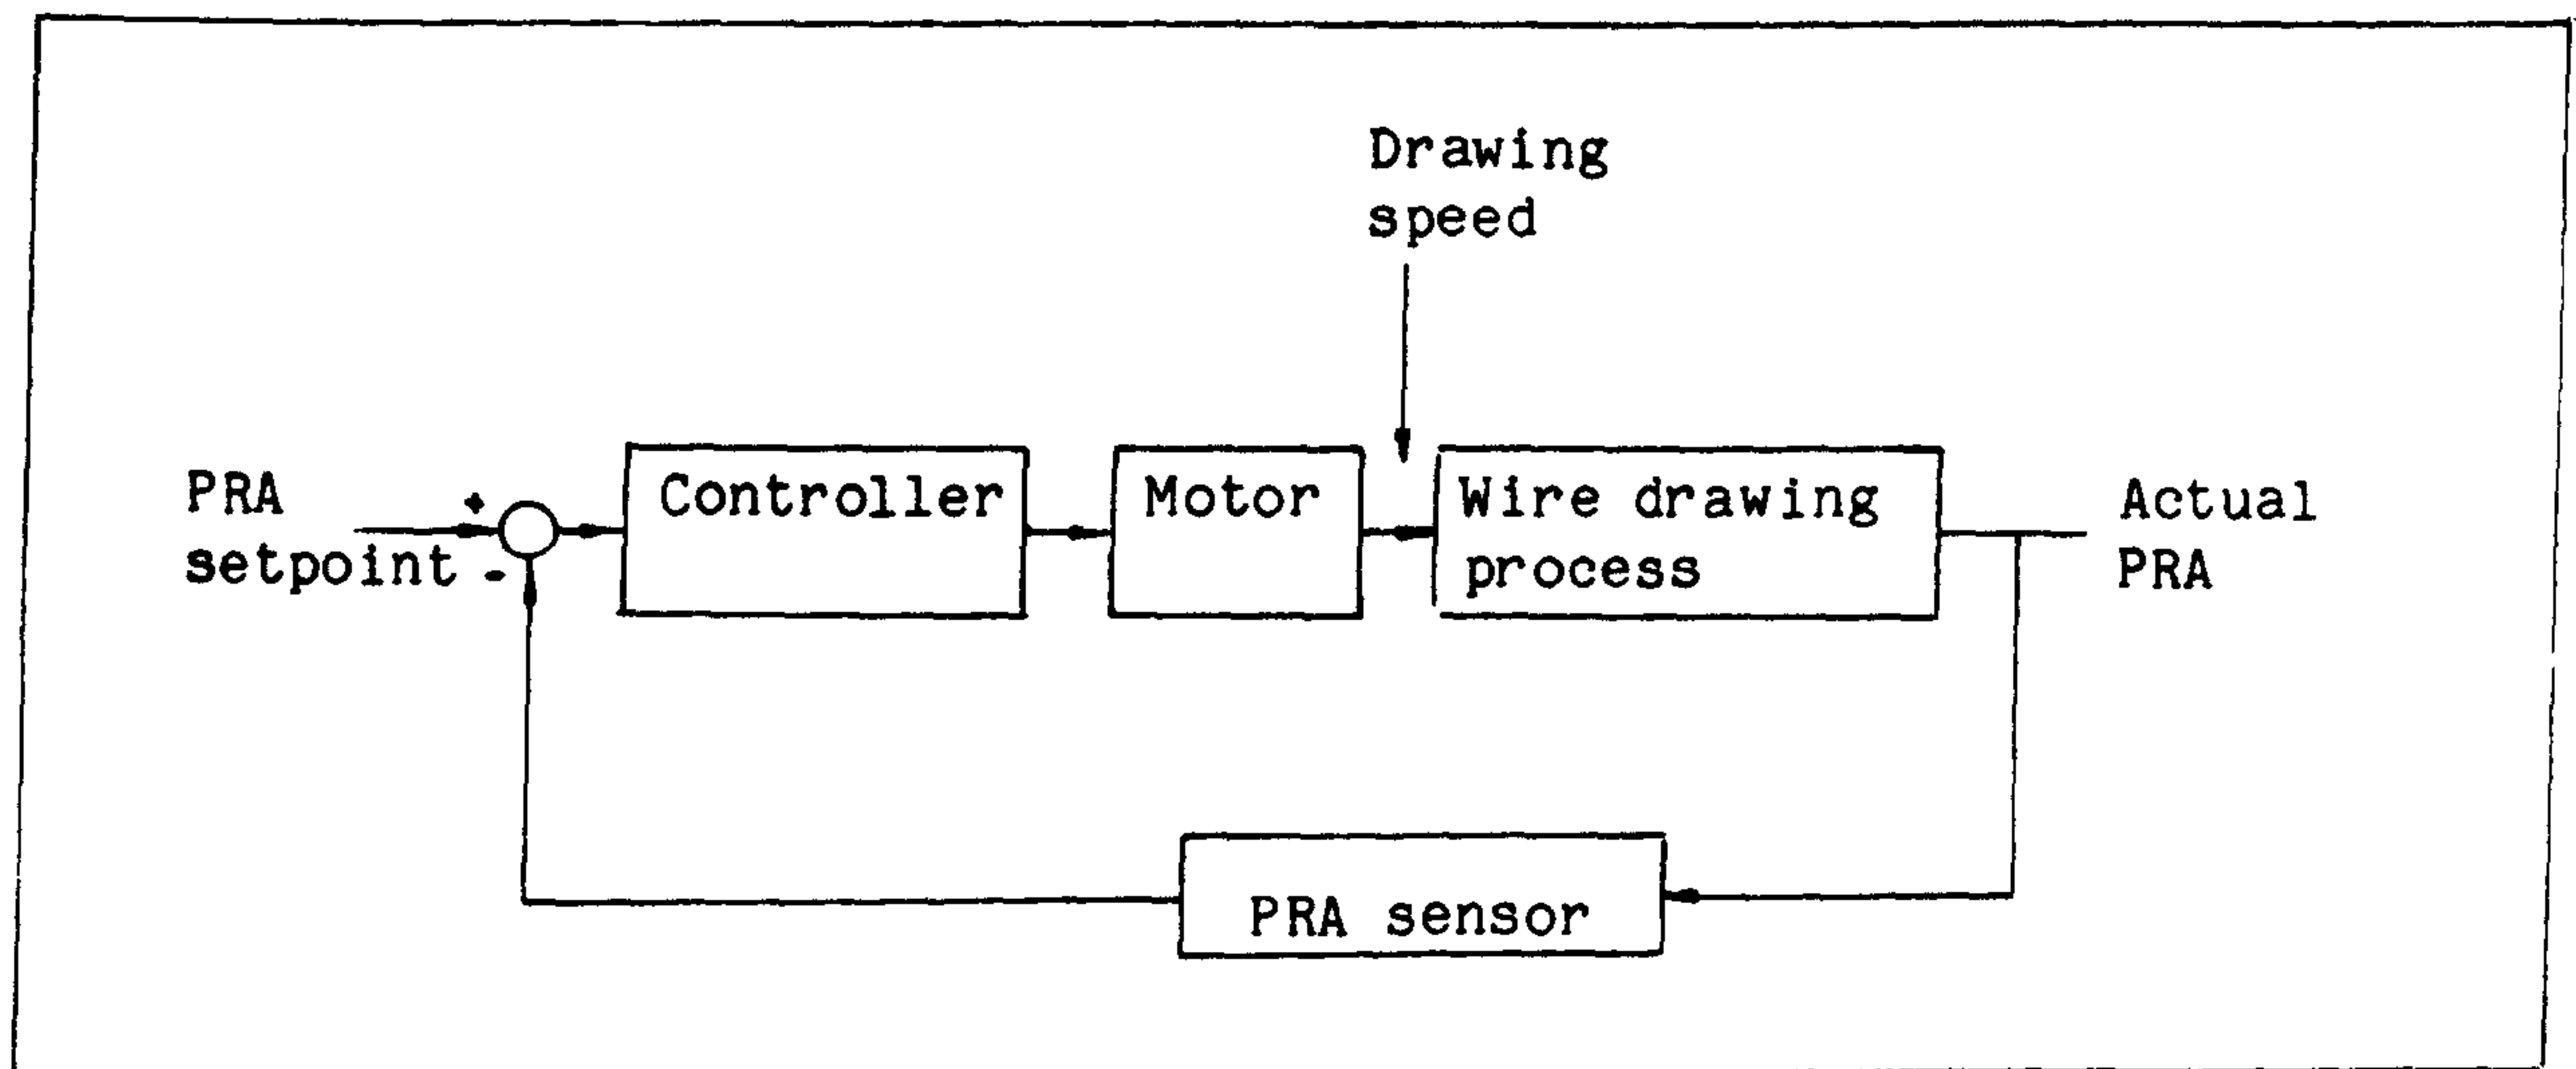

Fig. 3.8 Closed-loop Control system

In Fig. 3.8, the drawing speed is a manipulated variable, the PRA is a controlled variable, and the temperature is kept at its preselected value during the whole drawing process. The heart of the control system is the sensor. After the wire leaves the DRU, there is a polymer coating on the surface of the wire which remains as a protective cover of the product. Thus, there is not a simple method to directly measure the PRA of the wire due to this coating on its surface. A method which can measure the PRA of the wire during the drawing process has been designed and constructed, and this is described in section 3.7.

Further, a simpler configuration was taken into consideration. The theoretical and experimental results showed that the reduction in area of the wire remained constant provided that both the temperature of the polymer melt and the drawing speed were kept constant throughout the test. A unique value of the PRA thus existed for a particular

temperature and drawing speed. This suggested that an open-loop system for the reduction control in combination with two closed-loop systems for drawing speed and temperature control might be used to maintain the quality of the products. A system was therefore designed in which open-loop control was implemented for the PRA using experimental results in the form of look-up tables in the microcomputer memory locations. From these, both temperature and drawing speed for a given polymer corresponding to a required PRA could be found. After the required specification was input into the microcomputer via a keyboard, the microcomputer would automatically set the temperature, and then start the drawing process with a selected speed from the look-up tables to obtain the required product. The temperature and drawing speed were each controlled by a closed-loop control system, but the setpoints of the two systems were given by the microcomputer, so that each individual loop was operated in such a way as to produce the required wire. The sensor to detect the PRA was not included in the whole system at this stage. Experimental results showed that the quality of the product achieved the desired level with this control configuration. Fig. 3.9 shows the schematic diagram of the control system.

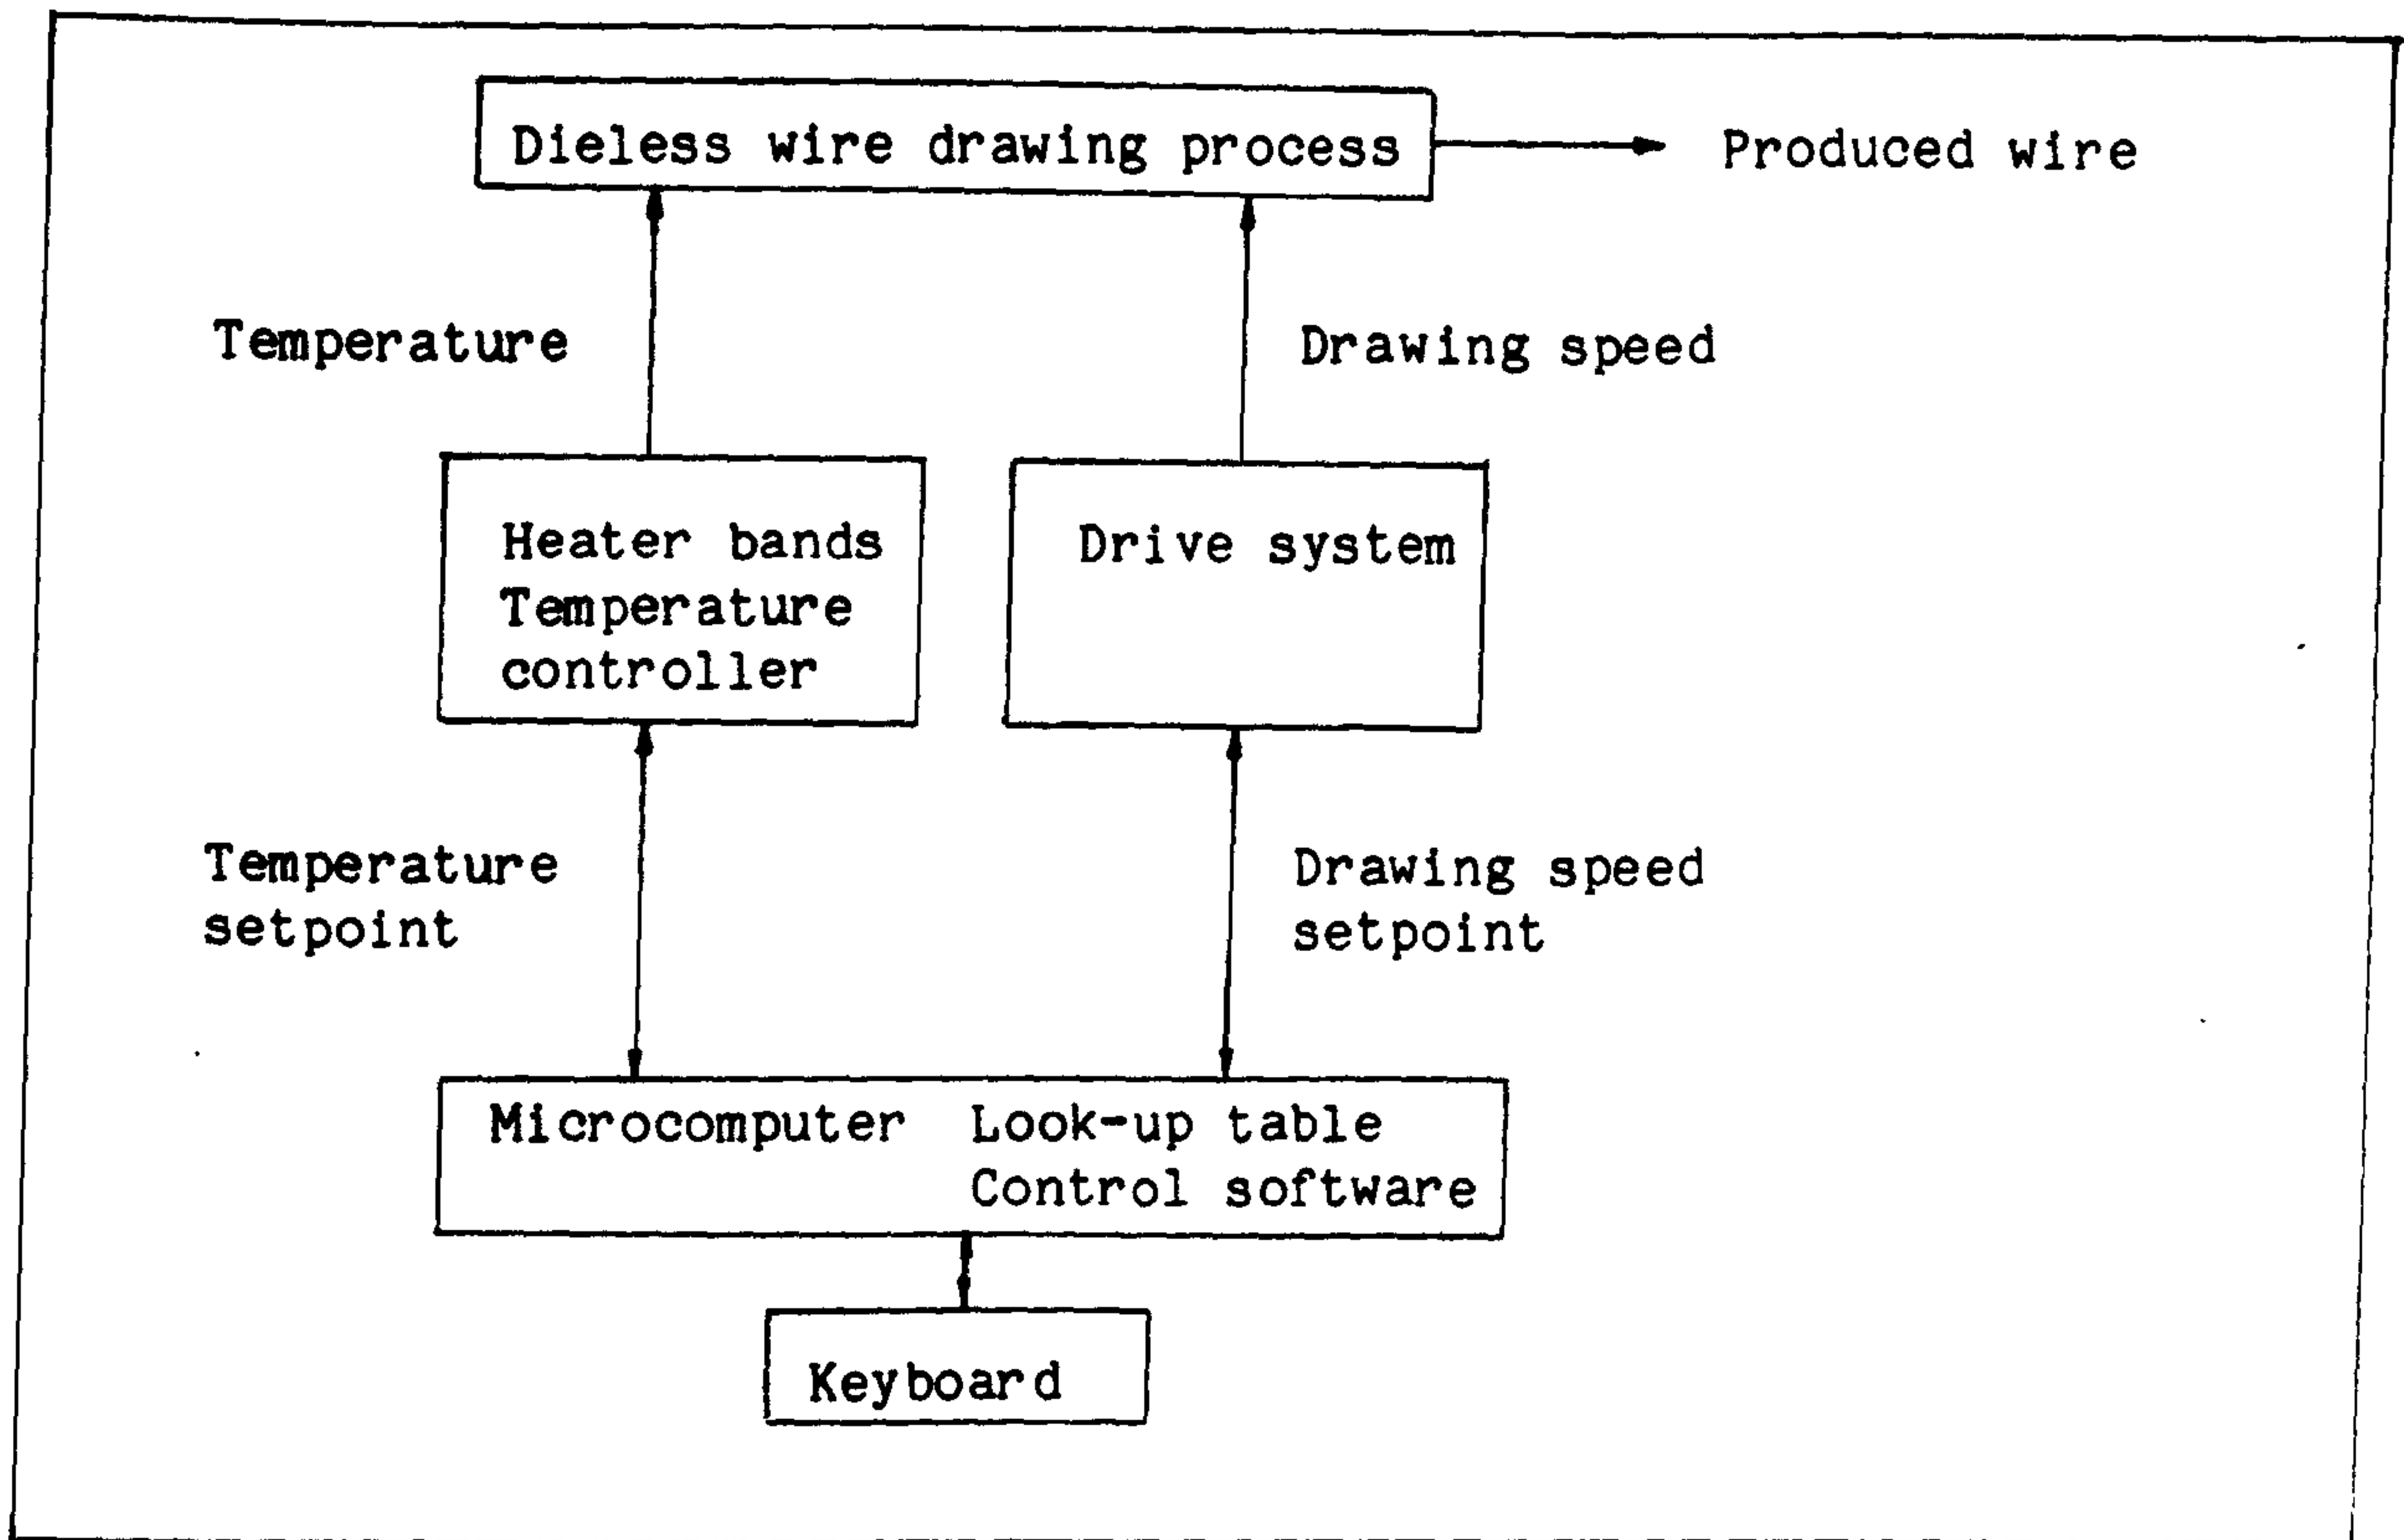

Fig. 3.9 Schematic Diagram of the Control System

3.2 - Description of the Experimental Equipment

The existing dieless wire drawing system as shown in Fig. 3.10 was designed by Dr. H. Parvinmehr. Wire from the coil placed on the stand was passed through the guides and over the pulley, and then pulled through the polymer feeder-DRU assembly and then wound onto the bull block. The detail of the polymer feeder-DRU assembly is shown in the schematic diagram of Fig. 3.11.

The undeformed wire passed through the polymer melt chamber before undergoing deformation within the DRU. The melt chamber was kept filled with polymer which was melted by means of an electric heater band. Because the polymer melt chamber could only store a limited amount of polymer, a hopper was mounted on the melt chamber having sufficient capacity to supply the chamber for a complete series of tests. The

hopper was also heated by an electric heater band and the temperature of the polymer melt within the chamber and the hopper was controlled thermostatically within $\pm 3^{\circ}\text{C}$ of the set temperature. This was achieved by use of thermocouples connected to controlled power supplies which fed electrical power to the heater bands. A digital thermometer was connected to the thermocouples to give a temperature display.

The hopper was also connected to a pressurized air supply of 100 psi via a 2-way servo valve. Hence the air pressure was activated onto the polymer surface, helping the polymer to flow with the wire into the DRU.

The original drawing bench consisted of interchangeable bull blocks of 50, 100 and 300 mm diameter, driven by a Schrage 3-phase electric motor capable of running at speeds between 550 and 2200 revolutions per minute. Since this was considered virtually impossible to control automatically with a microcomputer, the drive system was completely redesigned to incorporate a bull block of 300 mm diameter driven by a hydraulic motor (type OMP 50) capable of running at speeds infinitely variable between 0 and 800 revolutions per minute. The power was transmitted from the motor to the bull block via a 29:3 reduction worm gear box (CROFT type 41/551/05) and a coupling clutch (BROADBENT type DP25) which enabled the bull block to be engaged when the hydraulic motor was running at the required speed, thus providing some flexibility during the tests. The above arrangements facilitated drawing speeds infinitely variable between 0 and 1.3 ms^{-1} .

The above equipment was mounted on a suitable bench of welded steel construction and guarding was placed around all moving parts to provide adequate safety.

The rotational speed of the hydraulic motor was measured by coupling a tachogenerator (type AM 363) to the gear box rotating shaft. The feedback signal from the tachogenerator was transmitted into the

3.3 - Microcomputer and I/O Interface Circuit

The microcomputer used to implement the automatic control system was based on an MC68000 microprocessor. Fig. 3.13 shows the functional block diagram of the microcomputer.

The microcomputer includes:

- a) 4-megahertz MC68000 16-bit MPU
- b) 32k bytes of dynamic RAM and 16k byte firmware ROM / EPROM monitor.
- c) Two serial communication ports for a terminal and a host. Both are RS-232 compatible and have selectable baud rates.
- d) A parallel port which can be used for I/O or for a printer interface.
- e) Audio tape serial I/O port.
- f) Self-contained operating firmware that provides monitor, debug and disassembly / assembly functions.
- g) 24-bit programmable timer.
- h) Wire-wrap area provided for custom circuitry.
- i) Reset and Abort function switches.

The MC68000 based microcomputer was chosen for a number of reasons. The 24-bit timer can be programmed to generate interrupts to drive the execution of user's program. Multiply and divide operations are available for signed and unsigned operands using byte or word multiply to produce a word or a long product and a long word dividend with word divisor to produce a word quotient with a word remainder. This makes it possible to optimise 8-bit fixed-point or 24-bit floating-point arithmetic, resulting in a short execution time of the user's program, which can often meet the requirement of the sampling period for a real-time process control. The wire-wrap area on the microcomputer board facilitates convenient interface between the microcomputer and the process. The self-contained operating firmware of monitor, debug and disassembly / assembly functions provides the fundamentals of

man-machine conversation. Also there is a substantial support available both in hardware and software. All of these indicate that the MC68000 microcomputer is appropriate to be used to implement the control system of the dieless wire drawing process.

The main parts of the interface circuit will be described in the following paragraphs.

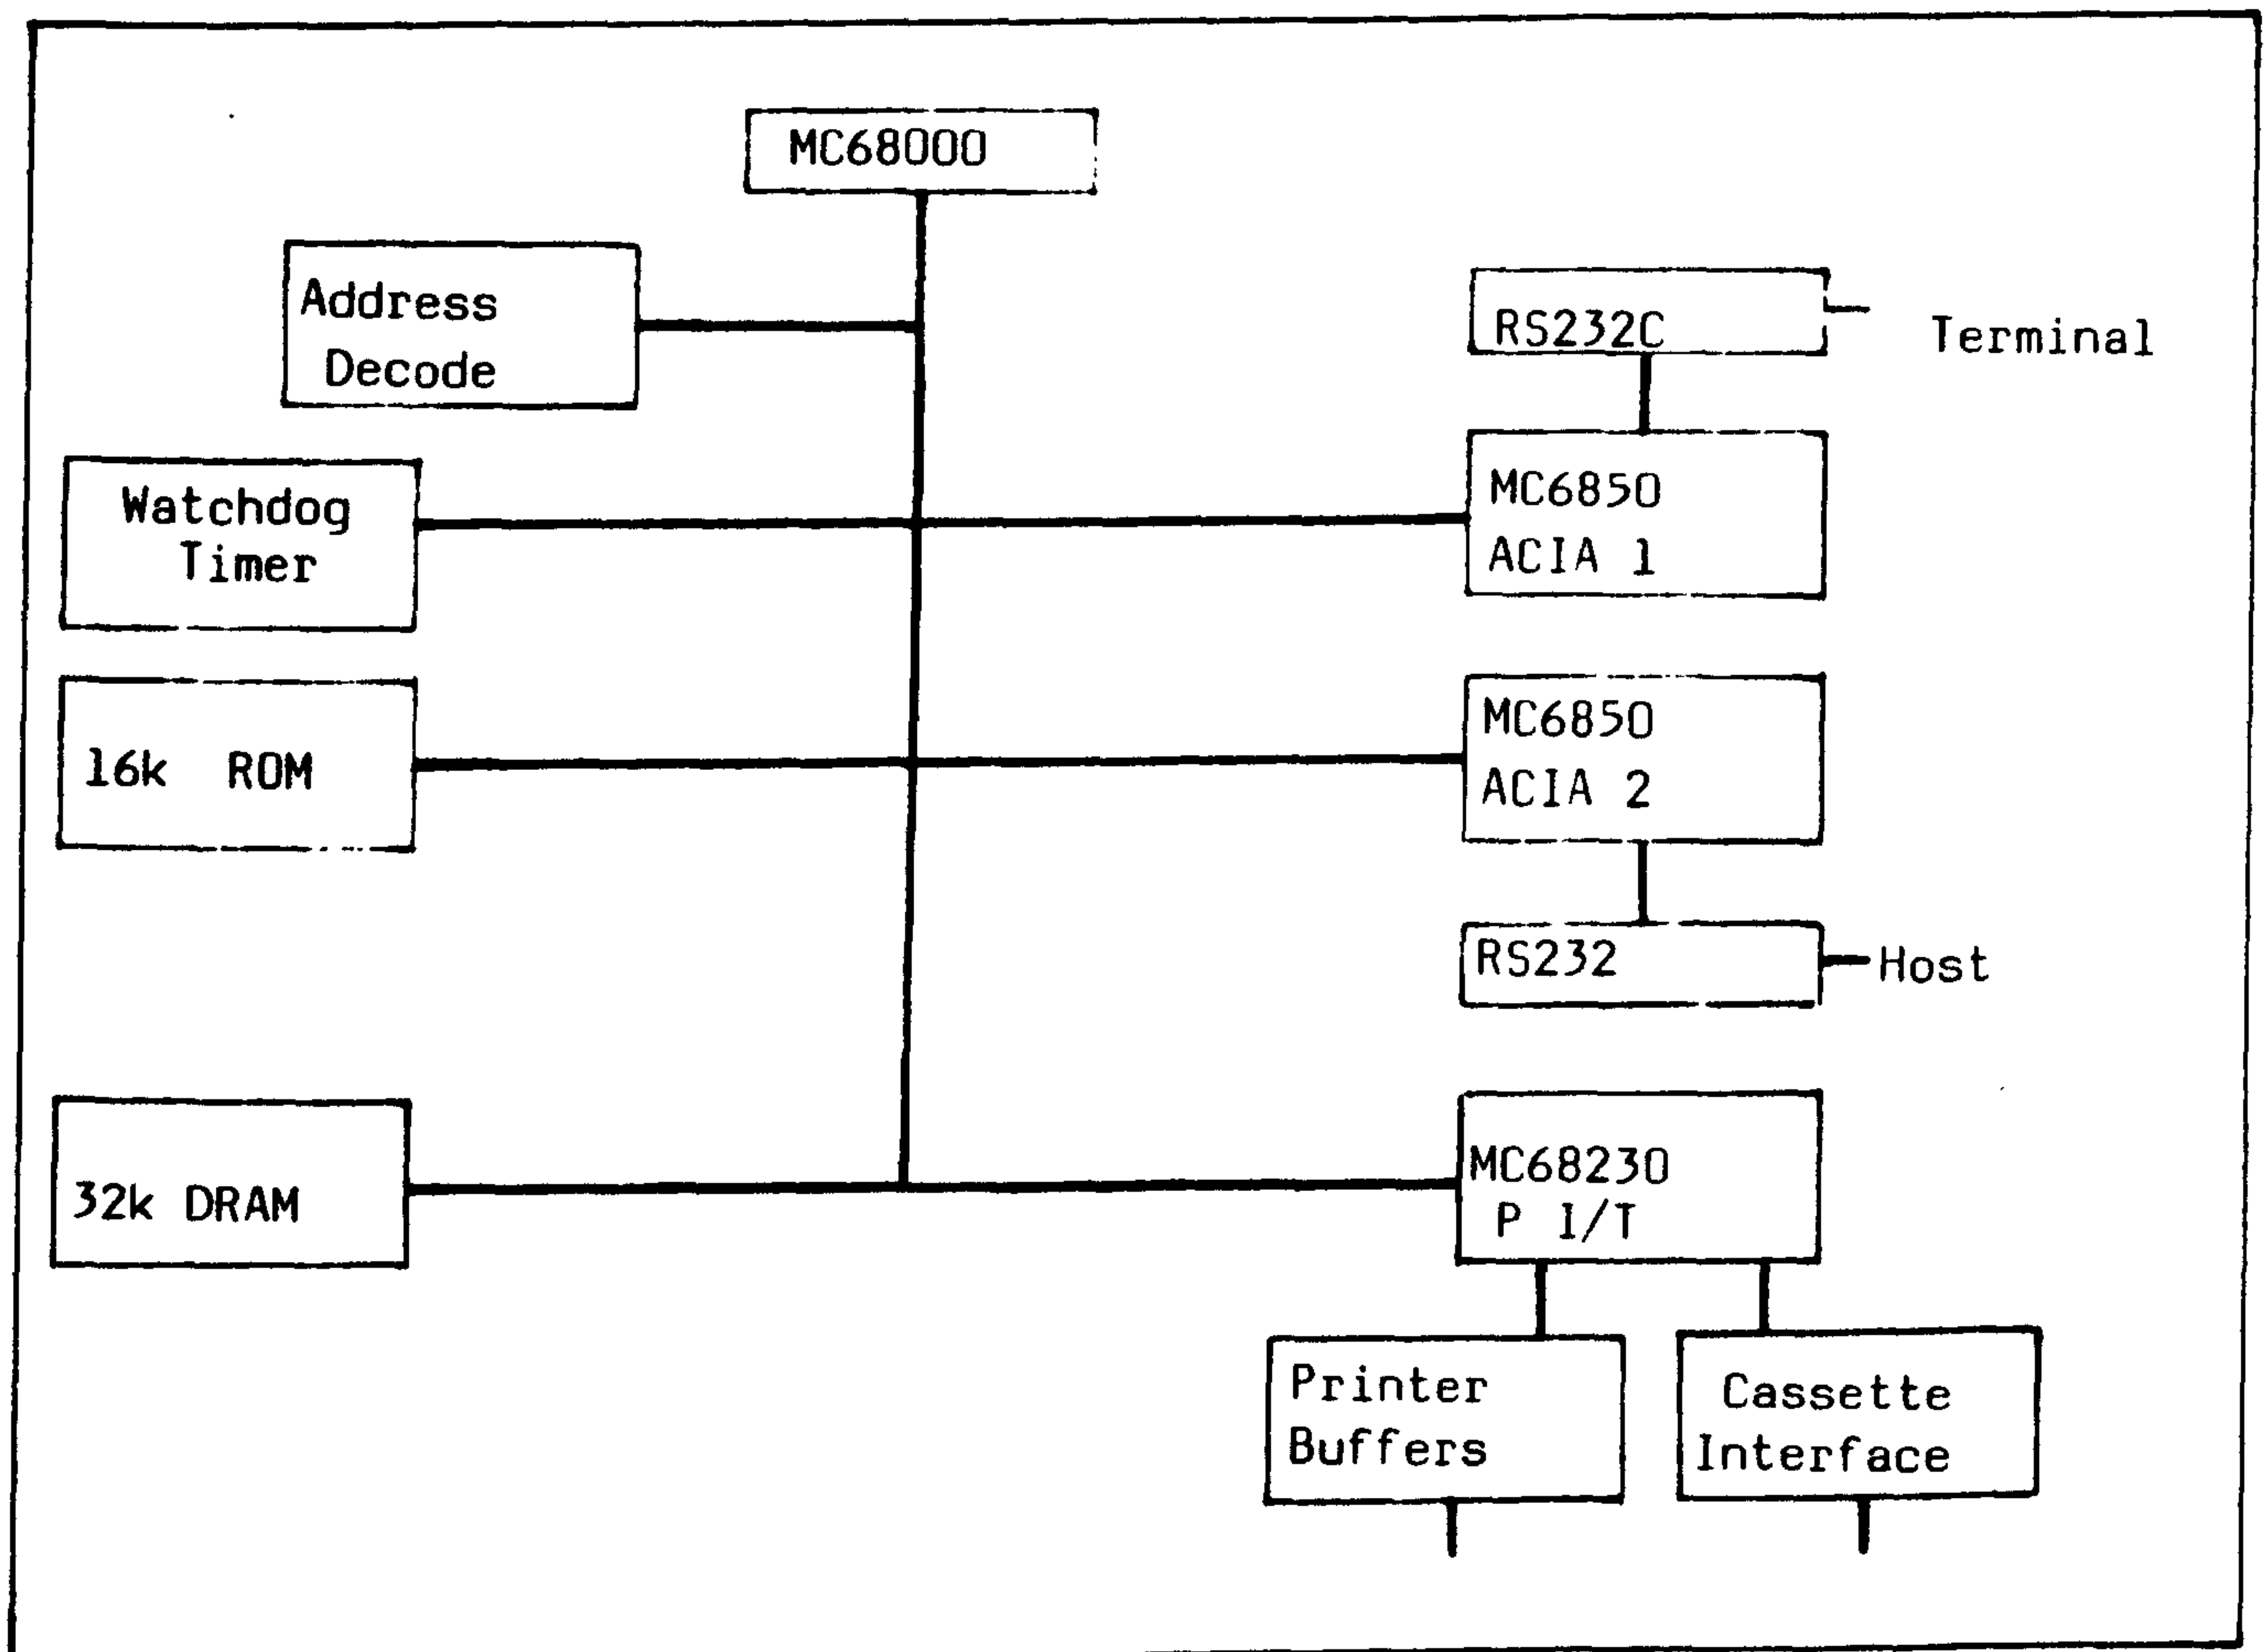

Fig. 3.13 Functional Block Diagram of MC68000 Microcomputer Board

3.3.1 - Interface to Speed and Temperature Control Systems

MC6821 Peripheral Interface Adapter (PIA) [15]

The block diagram of the MC6821 peripheral interface adaptor is shown in Fig. 3.14. It provides universal means of interfacing

peripheral equipment to the MC6800 or MC68000 microprocessor unit with 8-bit bidirectional data bus (D0-D7) for communication with the MPU, two bidirectional 8-bit buses (PA0-PA7, PB0-PB7) for interface to peripherals, three chip select lines (CS0, CS1 and $\overline{\text{CS2}}$), two register select lines (RS0 and RS1), two interrupt request lines ($\overline{\text{IRQA}}$ and $\overline{\text{IRQB}}$), Read / Write line (R/ $\overline{\text{W}}$), enable line, reset line, interrupt input lines (CA1 and CB1) and peripheral control lines (CA2 and CB2). These signals, in conjunction with the MC68000 $\overline{\text{VMA}}$, $\overline{\text{VPA}}$ and E three signals, permit the MPU to have complete control over the PIA and interface with peripheral equipment.

PIA Address Decode

A 64k-byte segment of the system map is reserved for an MC6800 type interface in the MC68000 microcomputer board. The MC6800 page enable E6 is activated when memory page \$030000-\$03FFFF is selected and both $\overline{\text{VMA}}$ and $\overline{\text{LDS}}$ are asserted. Fig. 3.15 shows the logic generating signal E6. The memory page enable is first activated, which, in turn, activates $\overline{\text{VPA}}$. After the MC68000 receives $\overline{\text{VPA}}$, the processor synchronizes itself to the E clock and continues the bus cycle by asserting $\overline{\text{VMA}}$. Signal E6 recognizes that the MC6800 page has been selected, $\overline{\text{VMA}}$ has been asserted for a synchronous cycle, and the $\overline{\text{LDS}}$ is asserted indicating a bus transfer on the lower eight data bus bits. Thus, the PIA must be interfaced into the lower eight bits of the data bus when using signal E6. The interfacing PIA chips to the MPU is shown in Fig. 3.17, where PIA1 is interfaced to the speed control system and PIA2 is interfaced to the temperature control system.

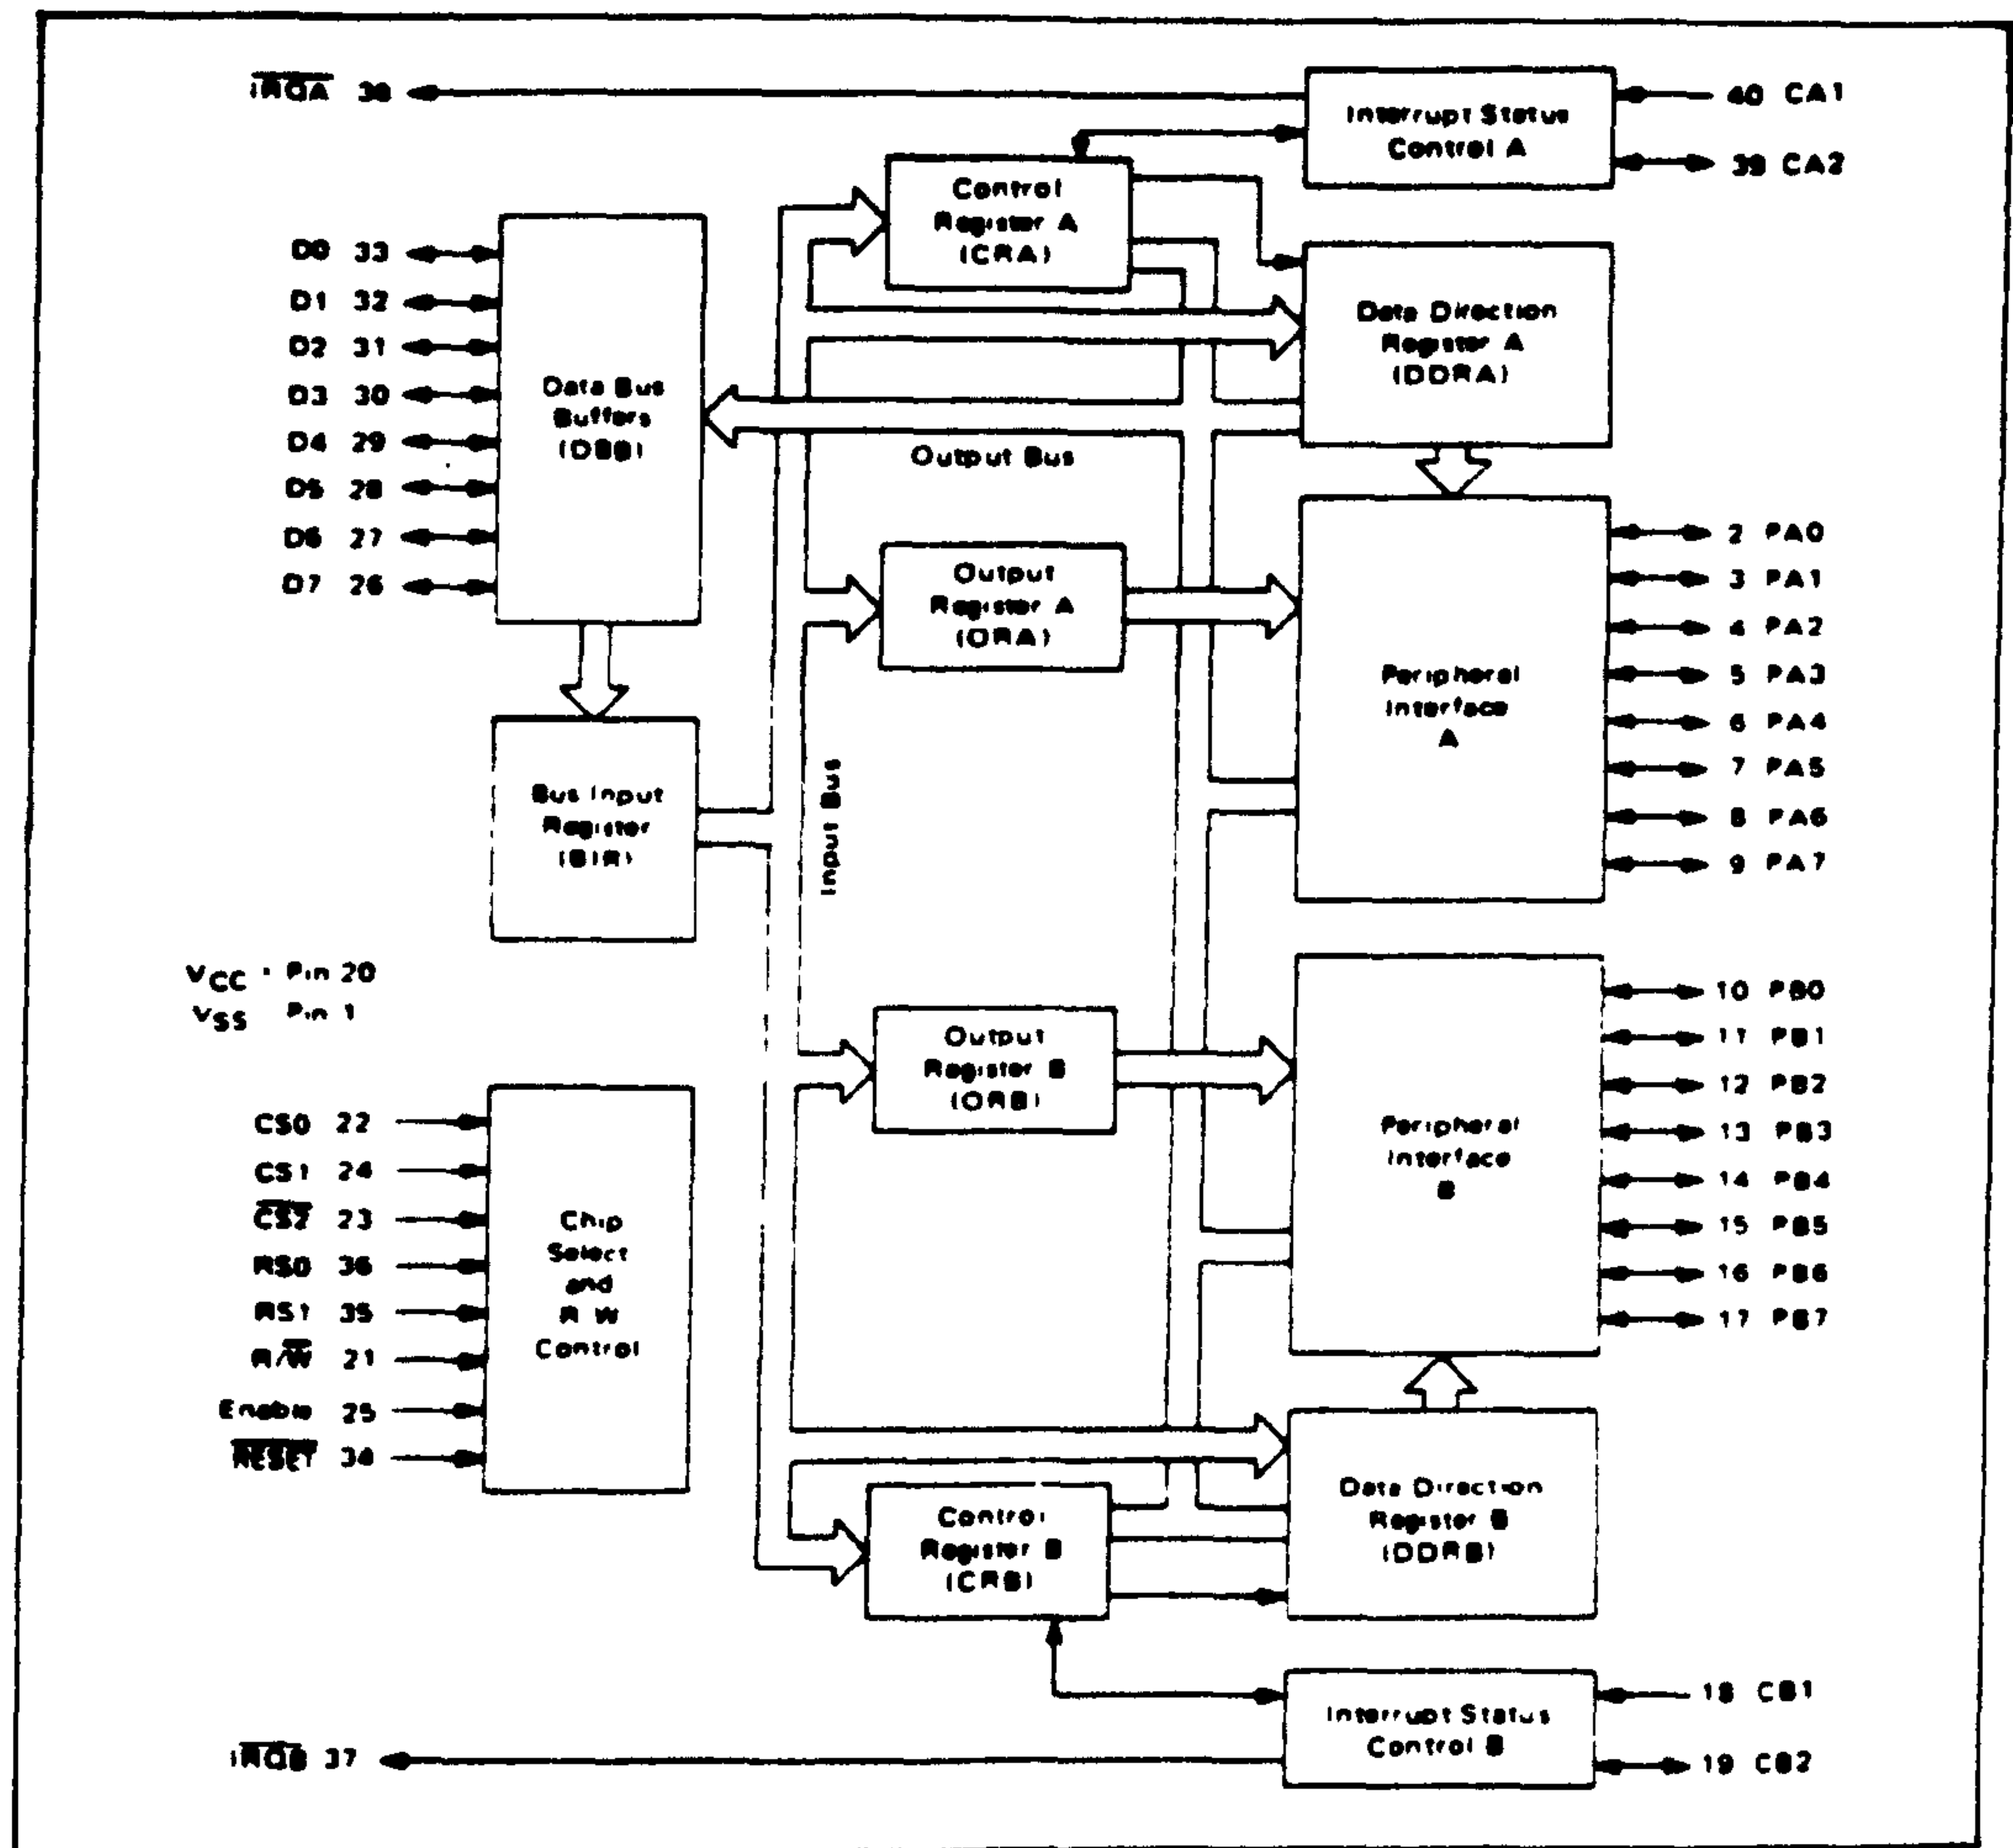

Fig. 3.14 Block Diagram of MC6821

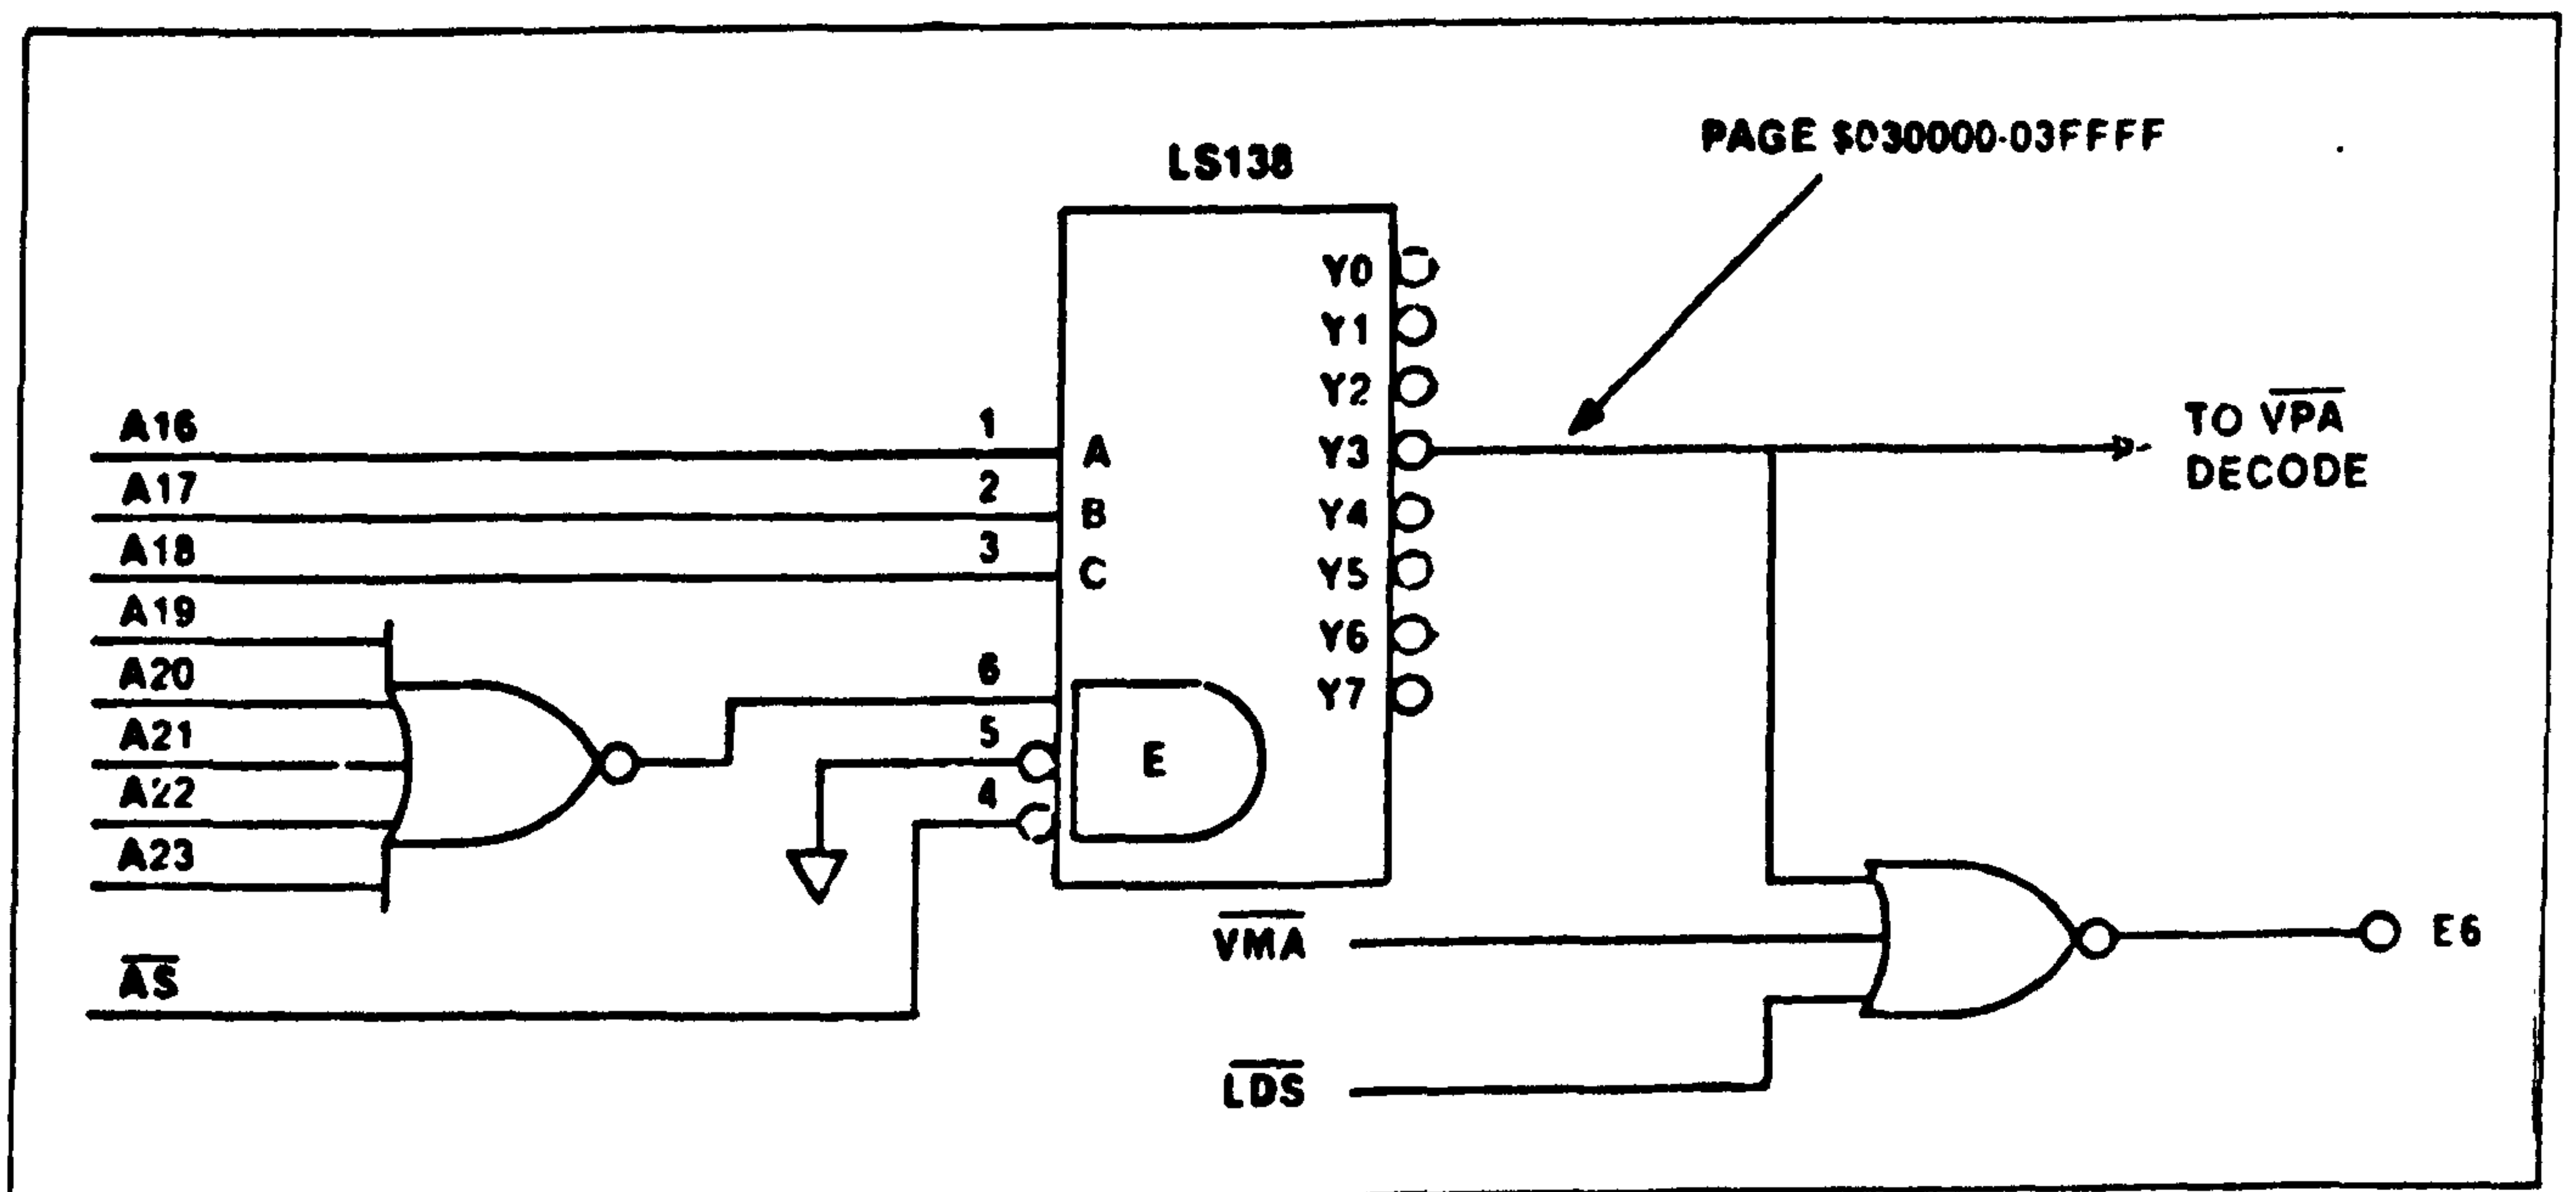

Fig. 3.15 MC6800 Page Address Signal Generation

There are six locations within the PIA accessible to the MPU data bus: two peripheral registers (PRA and PRB), two data direction registers (DDRA and DDRB), and two control registers (CRA and CRB). Selection of these locations is controlled by RS0 and RS1 (see Fig. 3.14) inputs together with bit2 in the control register, as shown in Table 3.1.

Table 3.1 PIA Internal Addressing

RS1	RS0	Control Register Bit		Location Selected
		CRA2	CRB2	
0	0	1	*	Peripheral Register A
0	0	0	*	Data Direction Register A
0	1	*	*	Control Register A
1	0	*	1	Peripheral Register B
1	0	*	0	Data Direction Register B
1	1	*	*	Control Register B

Table 3.2 gives the PIA1 and PIA2 address map in detail.

Table 3.2 PIA Chips Address Decoding

Register		Address bus Bit								Address Decode
		A7	A6	A5	A4	A3	A2	A1	A0	
PRA1	DDRA	1	1	1	1	*	0	0	*	\$03FFF8
	CRA	1	1	1	1	*	0	1	*	\$03FFFA
	DDRB	1	1	1	1	*	1	0	*	\$03FFFC
	CRB	1	1	1	1	*	1	1	*	\$03FFFE
PRA2	DDRA	1	1	1	0	*	0	0	*	\$03FFE8
	CRA	1	1	1	0	*	0	1	*	\$03FFEA
	DDRB	1	1	1	0	*	1	0	*	\$03FFEC
	CRB	1	1	1	0	*	1	1	*	\$03FFEE

Note: * undefined

Each of the peripheral data lines can be programmed to act as an input or output. This is accomplished by setting a "1" in the corresponding data direction register bit for those lines which are to be outputs. A "0" in a bit of the data direction register causes the corresponding peripheral data line to act as an input. The following program is an example of configuring a PIA and data access.

```
* MC68000
* Initialization of port A as input
* Initialization of port B as output

    MOVE.B  #0,  CRA
    MOVE.B  #0,  DDRA
    MOVE.B  #4,  CRA      ; Port A = input
    MOVE.B  #0,  CRB
    MOVE.B  #$FF,DDRB
    MOVE.B  #4,  CRB      ; Port B = output

* Input data to register D1 via port A
IN: MOVE.B  PRA, D1

* Output data from D1 via port B
OU: MOVE.B  D1,  PRB
```

Analogue-Digital Conversion

An 8-bit ADC ZN449 is used to convert analogue signal to digital value [16] (see Fig. 3.17). It is a successive approximation converter with 9 μ s conversion time. Fig. 3.16 shows analogue-digital converter timing. Upon receipt of a negative-going pulse at the WR input, the BUSY output goes low and the conversion starts. On the eighth negative edge of the clock pulse BUSY goes high indicating that the conversion is complete. Data can be read by taking RD low to enable the 3-state outputs.

Fig. 3.16 ZN449 Analogue-Digital Converter Timing

Handshaking Between the PIA and the ADC

The control register CRA within the PIA allows the MPU to control the operation of the two peripheral control lines CA1 and CA2. In addition it allows the MPU to enable interrupt line ($\overline{\text{IRQA}}$) and monitor the status of the interrupt flags. Bits 0 to 5 of the CRA may be written or read by the MPU when the proper chip select and register select signals are applied. Bit6 and Bit7 of the CRA are read-only and are modified by external interrupts occurring on control lines CA1 and CA2. The format of the control words is shown in Table 3.3.

Table 3.3 Control Word Format of CRA

7	6	5	4	3	2	1	0
IRQA1	IRQA2	CA2 Control			DDRA Access	CA1 Control	

Bits 3, 4 and 5 of the CRA are used to control the CA2 peripheral control line. These bits determine if the CA2 will be an interrupt input or an output control signal. Table 3.4 gives the format of the three bits when CA2 works in the output mode to control peripheral data transfer.

Table 3.4 Control of CA2 as an Output

CRA5 CRA4 CRA3			CA2	
			Cleared	Set
1	1	0	Low when CRA3 goes low as a result of an MPU write to control register A	Always low as long as CRA3 is low. Will go high on an MPU write to control register A that changes CRA3 to 1
1	1	1	Always high as long as CRA3 is high. Will be clear on an MPU write to control register A that clears CRA3 to 0	High when CRA3 goes high as a result of an MPU write to control register A

In Fig. 3.17, CA2 is used to generate a negative-going pulse at the WR input of the ADC as a conversion starting signal. Bit0 and bit1 of the CRA are used to control the interrupt input line CA1. Bit CRA0 is used to enable the MPU interrupt signal $\overline{\text{IRQA}}$. Bit CRA1 determines the active transition of the interrupt input signal CA1. The format of the two bits is given in Table 3.5.

Table 3.5 Control of Interrupt Input CA1

CRA1 CRA0	Interrupt Input CA1	Interrupt Flag CRA7	MPU Interrupt Request IRQA
1 0	↓ Active	Set high on of CA1 ↓	Disable IRQ remains high
1 1	↑ Active	Set high on of CA1 ↑	Goes low when the interrupt flag bit CRA7 goes high

Note: ↑ indicates positive transition

In Fig. 3.17, CA1 is connected to the BUSY line of the ADC. When conversion finishes, BUSY goes high, thus enabling CRA7 to go high. During the conversion period, the program will keep testing the value of bit CRA7. If CRA7 goes high, a data input instruction will be executed. The program which initiates the analogue-digital conversion and the data input is as follows.

```
* MC68000
* Initializing an analogue-digital conversion

CON:  MOVE.B #$36,  CRA    ; Disable interrupt, CA2 goes low
                                ; initializing A-D conversion
      NOP
      MOVE.B #$3E,  CRA    ; CA2 goes high
CON1:  BTST   #7,    CRA    ; If the conversion finishes
      BEQ    CON1      ;
      MOVE.B PRA,   D0     ; If bit CRA7 goes high, input
                                ; data to register D0
```

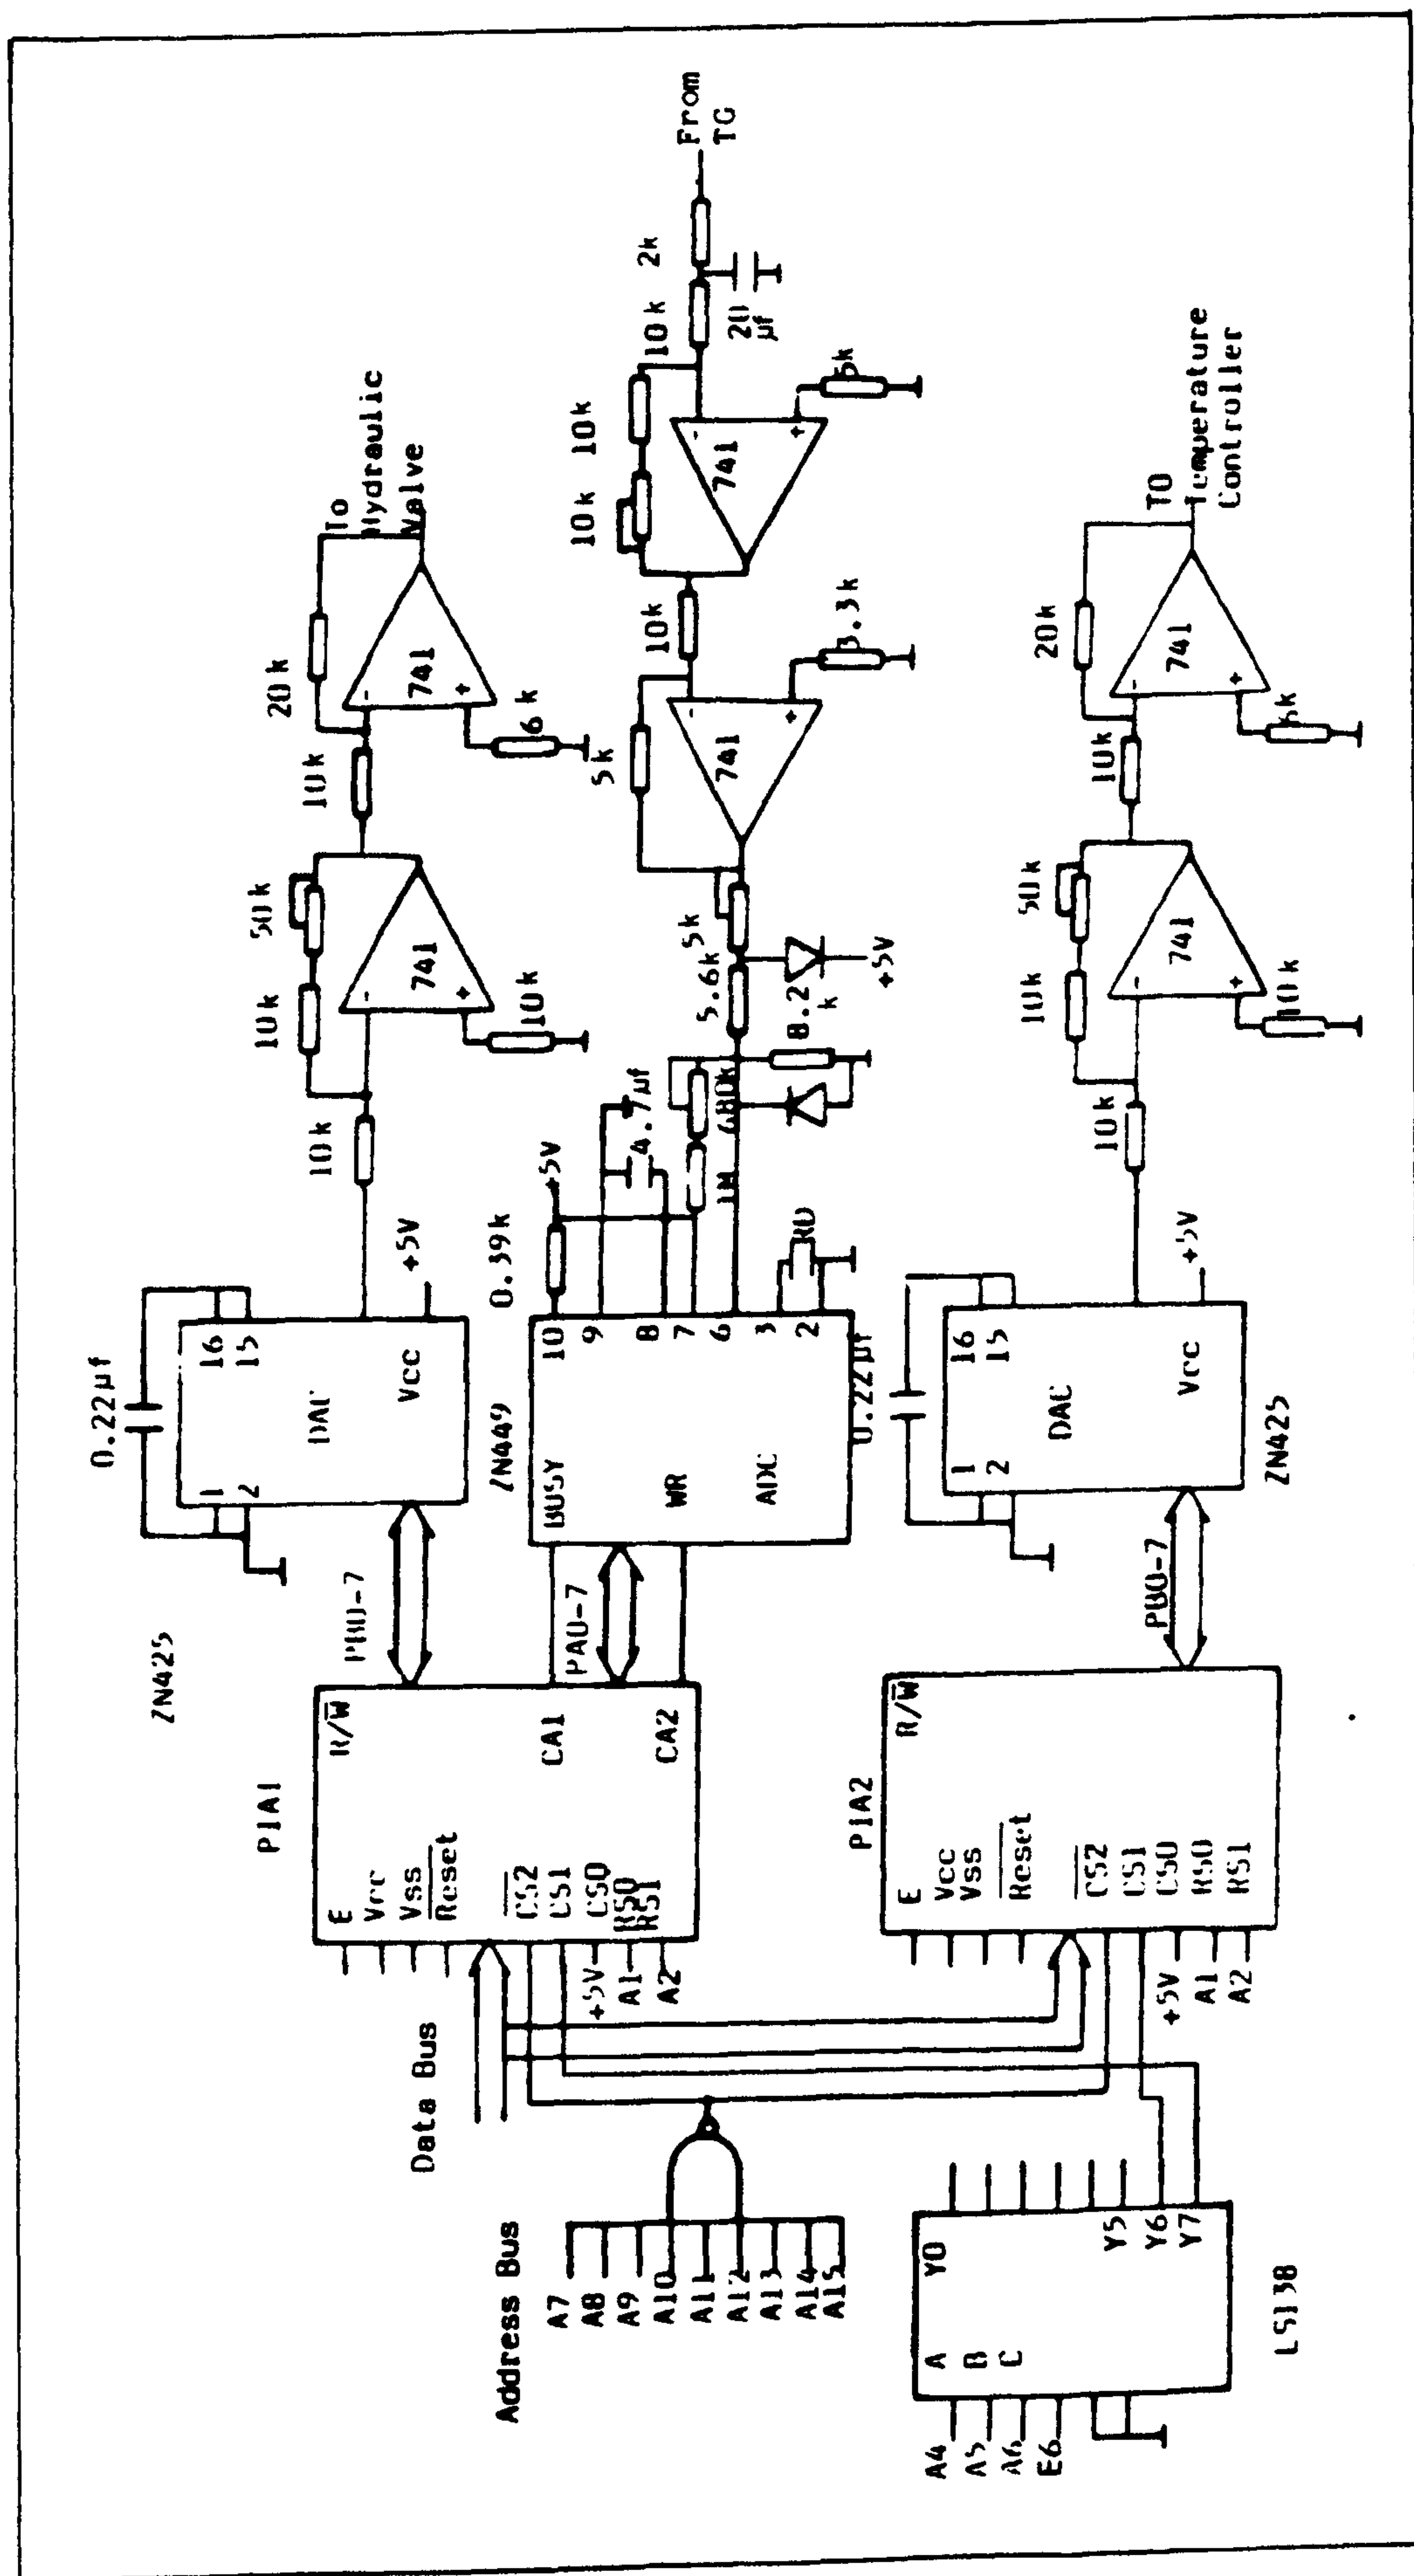

Digital-Analogue Conversion

Two 8-bit digital analogue converters (ZN425) [16] Were used to implement the digital-analogue conversions for speed and temperature sets respectively (see Fig. 3.17). The settling time of the DAC is 1 μ s, and the maximum output is 5 V corresponding to digital input \$FF.

Amplifier

Amplifiers ahead of the ADC and after the DAC were needed to match the magnitudes of the signals. As shown in Fig. 3.17, the amplifiers were simply built using 741 operational amplifiers.

Fig. 3.17 shows the arrangement of the interface circuit and Plate 3 shows the interface circuit board.

Plate 3

3.3.2 - Generation of Interrupts

The program which executed once in each successive sampling period was interrupt driven. In the MC68000 microcomputer board, an MC68230 parallel interface/timer (PI/T) (see Fig. 3.13) was available and it was programmed to generate a periodic vectored interrupt corresponding to the required sampling period.

Fig. 3.18 shows the MC68230 block diagram [17]. The on-board timer contains a 24-bit synchronous down counter that can generate periodic interrupts, a square wave, or a single interrupt after a programmed time period. The TOUT pin is connected to the MPU interrupt request circuitry and the TIACK pin is used as an interrupt acknowledge input to the timer. The TIN pin is connected to 4 MHz system clock. The PI/T timer is

loaded from three 8-bit counter preload registers (CPRH, CPRM and CPRL). The 24-bit counter (CRH, CRM and CRL) is clocked from the output of a 5-bit (divide-by-32) prescaler. The clock source is the system clock. The counter signals the occurrence of an event primarily through zero detection (a zero is when the 24-bit counter is equal to zero). This sets the zero detect status (ZDS) bit in the timer status register and generates a timer interrupt. The ZDS bit must be reset by writing a "1" to the timer status register in that bit position to enable next interrupt. Thus, when the 24-bit counter is loaded with \$FFFFFF, the interrupt interval reaches its maximum value $T = 134.22 \text{ s}$. The minimum interrupt interval is $8 \mu\text{s}$ with "1" loaded in counter preload registers. The timer is fully configured and controlled by programming an 8-bit timer control register (TCR) in the PI/T. The format of the TCR for generating periodic vectored interrupts is shown in Table 3.6.

Table 3.6 The TCR Format

Bit	7	6	5	4	3	2	1	0
	1	0	1	0	*	0	0	1

Bit

7 6 5

Value

1 0 1

The pin TOUT is used as a timer interrupt request output.

The pin TIACK is used as a timer interrupt acknowledge input. This combination supports vectored timer interrupts

Bit

4

Value

0

The counter is loaded from the counter preload register on the first clock to the 24-bit counter after zero detect, and resumes counting.

Bit

2 1

Value

0 0

Prescaler is clocked by the TIN pin input. The 24-bit counter is decremented or loaded from the CPR when the prescaler rolls over from \$0 to \$1F.

Bit	0	
Value	0	Disable timer
	1	Enable timer

To use the interrupts, an 8-bit vector number must be loaded into the timer interrupt vector register (TIVR) at the initialization stage. When an interrupt occurs, the MC68000 translates this 8-bit vector number into an address by multiplying the 8-bit number by four. At this address location, the starting address (32 bits) of the interrupt handler routine is stored. Table 3.7 gives the address map of the PI/T registers concerning interrupt generating.

Table 3.7 Address Map of the PI/T

Address	Register
\$010021	Timer control register (TCR)
\$010023	Timer interrupt vector register (TIVR)
\$010027	Counter preload register high (CPRH)
\$010029	Counter preload register middle (CPRM)
\$01002B	Counter preload register low (CPRL)
\$010035	Timer status register (TSR)

The program which enables the interrupt and the interrupt handler routine execution is described as follows.

```

* MC68000
* Initialization for interrupt generating

MOVE.B    #0, CPRH
MOVE.B    #9, CPRM
MOVE.B    #$C4,CPRL ; Set 20 ms interrupt interval
MOVE.B    #$1B,TIVR ; Load 8-bit vector number 1BH into the TIVR
MOVE.L    SB, $006C ; The starting address ( 32 bit ) of the
                    ; interrupt handler routine is stored in
                    ; the address location of $006C
MOVE.B    #$A1,TCR ; Initialize the TCR and enable the timer

* Interrupt handler routine

MOVE.B    #1, TSR ; Enable next interrupt

```

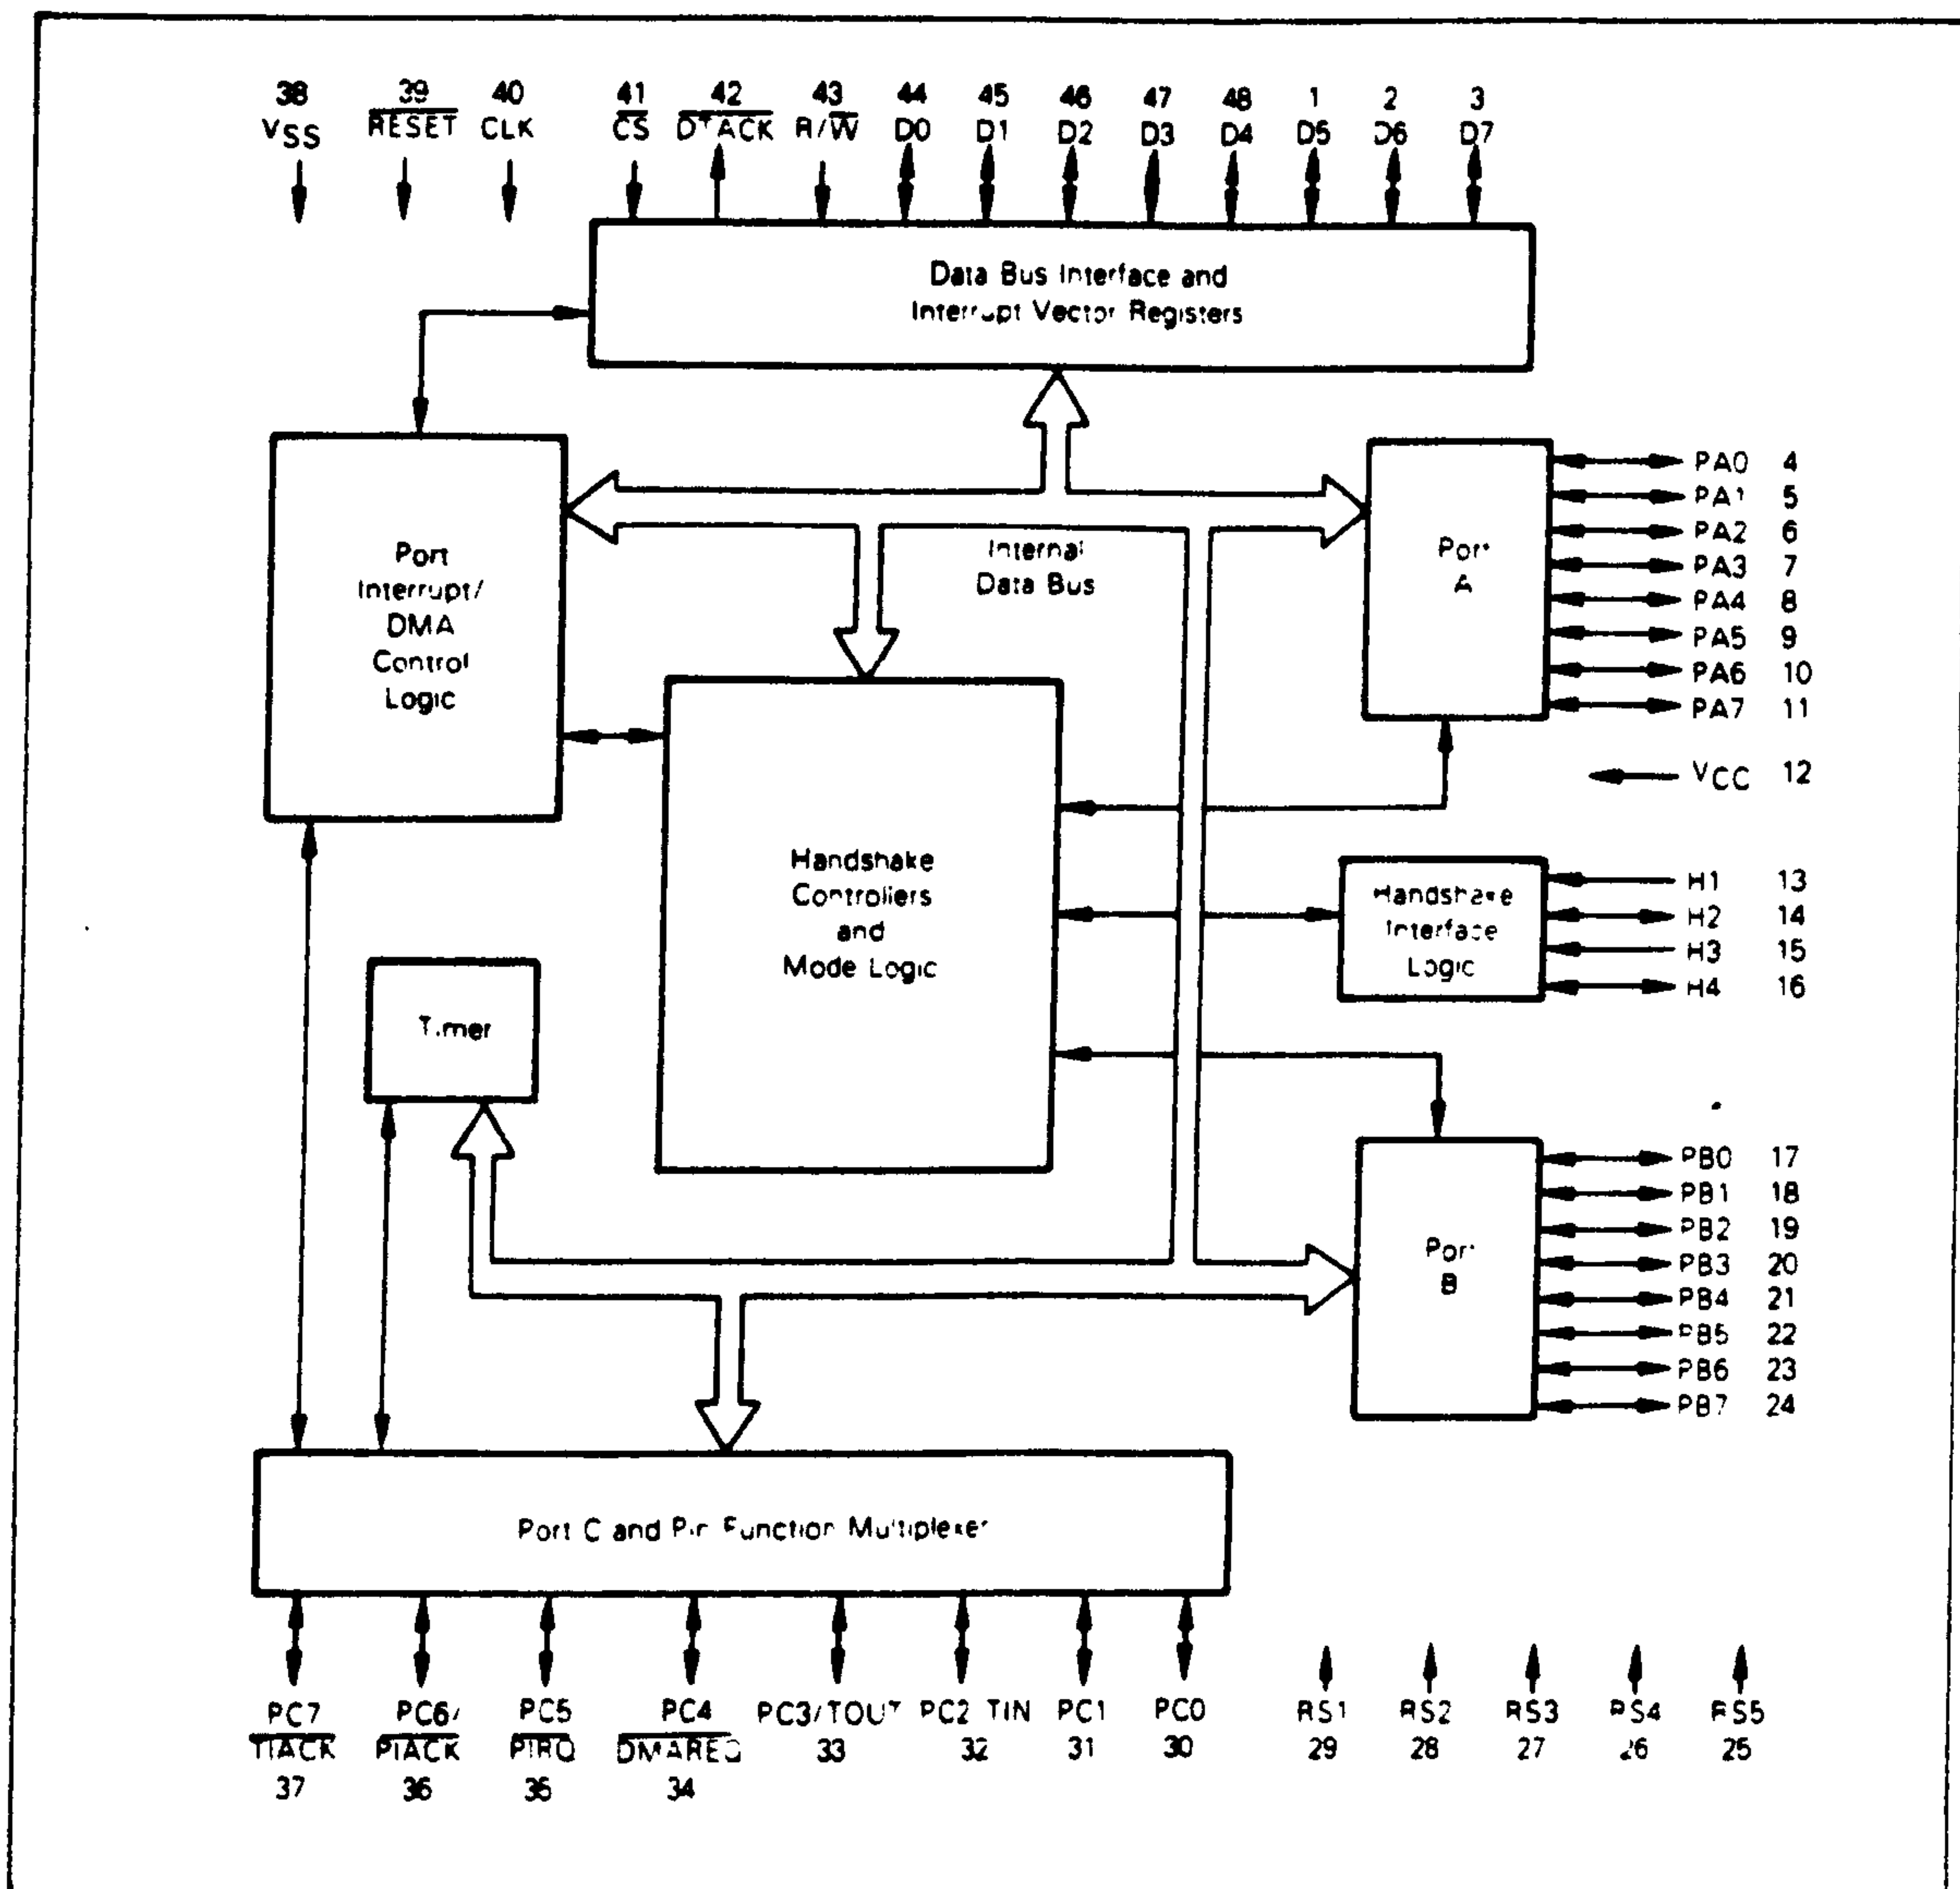

Fig. 3.18 Block Diagram of MC68230

3.4 - Temperature Control of the Polymer Melt

As mentioned before, both polymer hopper and polymer chamber were heated by electrical heater bands. A simplified method is taken here in evaluating the transfer function for the polymer hopper and the polymer chamber in order to design the control system. Fig. 3.19 shows the schematic diagram of the polymer chamber heating process.

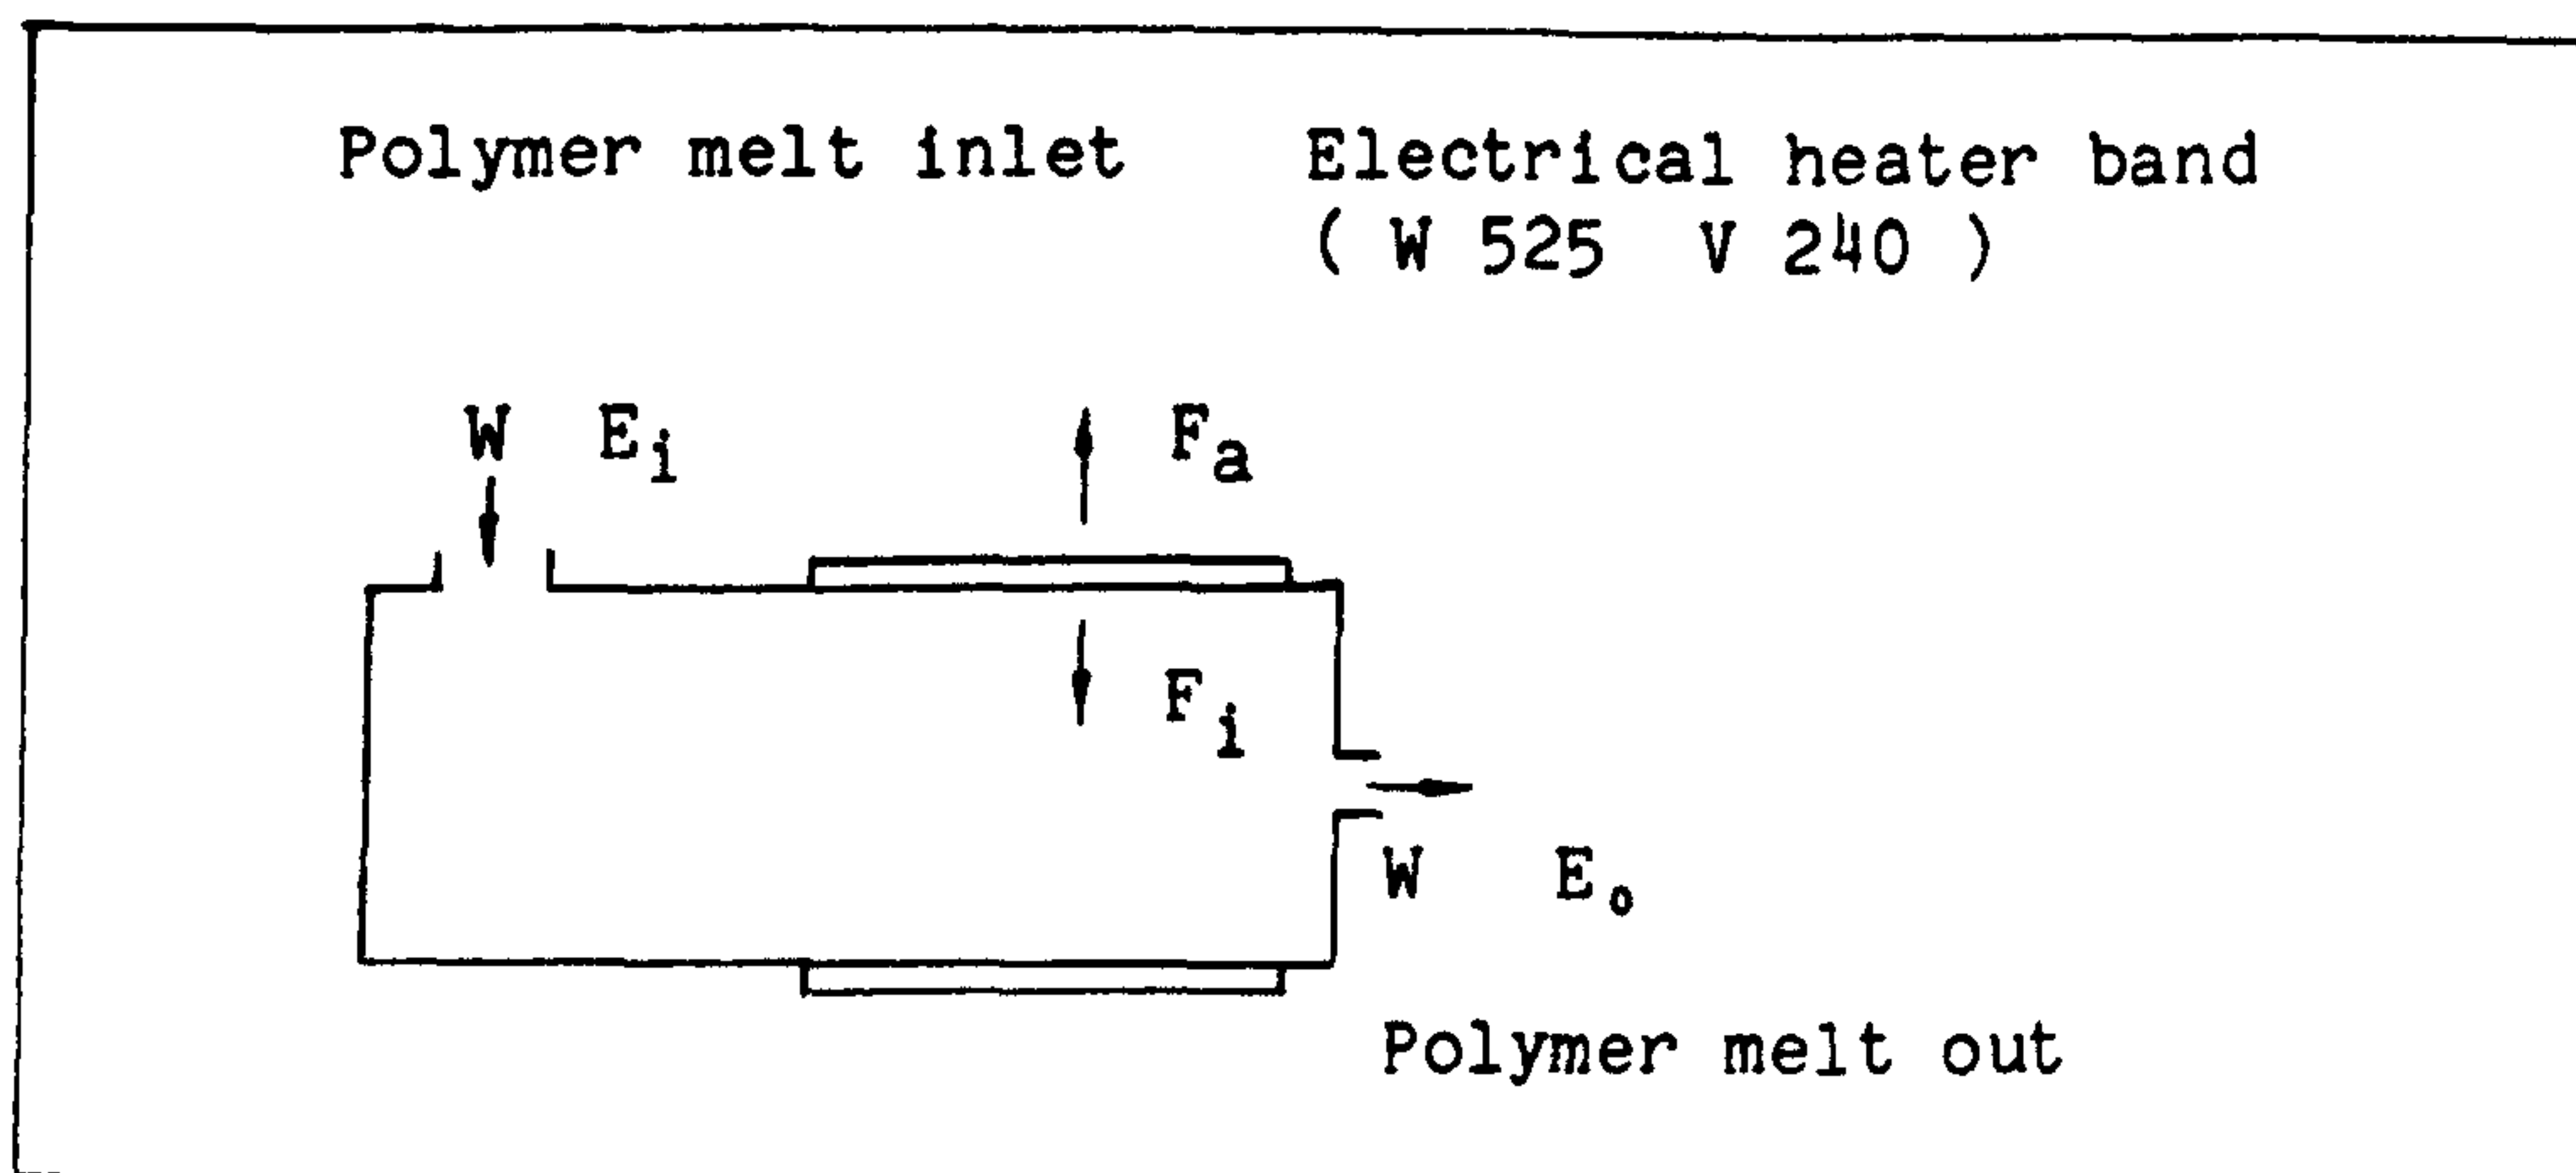

Fig. 3.19 Polymer Melt Chamber Heating Process

Where E_o the temperature of the polymer melt within the chamber.

E_i the temperature of entering polymer melt.

W the rate (both entering and leaving) of the polymer melt mass.

F_i the rate of heat supply from the electrical heater.

F_a the rate of heat loss to surroundings.

Note that the thermal parameters have been considered to be lumped [18], which means that the polymer melt temperature has been assumed to be uniform within the polymer chamber. If the temperature were to be considered as functions of both time and position, it would be necessary to describe the system by partial differential equations. However, in this case, the result derived from the lumped parameter model proved accurate enough for the design of the temperature control system. Under the assumption that a small change f_i occurs in F_i , and then it causes small changes in F_a and E_o , denoted by f_a and e_o respectively, the energy balance for the system gives

$$C \frac{de_o}{dt} = - f_a + f_i - C_p W e_o \quad (3.1)$$

Where C_p is the specific heat capacity of the polymer melt.

C is the capacitance of the polymer melt within the chamber,

$$\text{i.e., } C = G C_p$$

G is the mass of the polymer melt within the chamber

The capacity of the wall of the polymer chamber is negligible.

Taking Laplace transforms for equation (3.1) and assuming zero initial conditions yields equation (3.2).

$$E_0(s) = \frac{R F_i(s)}{1 + RCs} - \frac{R F_a(s)}{1 + RCs} \quad (3.2)$$

Where $R = 1 / C_p W$

Consider the heat loss as illustrated in Fig. 3.20

Fig. 3.20 Heat Loss to Surrounding

Taking the change of the ambient temperature E_a as zero and defining the constant $R_1 = 1 / A U$, where A is an effective heat transfer area and U is the overall convection heat transfer coefficient, we get

$$e_o = R_1 f_a \quad (3.3)$$

Taking Laplace transforms for equation (3.3) gives

$$E_0(s) = R_1 F_a(s) \quad (3.4)$$

Combining equation (3.2) and equation (3.4) gives

$$E_0(s) = \frac{R F_i(s)}{1 + RCs} - \frac{R E_0(s)}{R_1 (1 + RCs)} \quad (3.5)$$

Rearranging equation (3.5) gives

$$E_0(s) = \frac{R R_1 F_i(s)}{(R_1 + R) + R_1 R C s} \quad (3.6)$$

Now, since $F_i(s)$ can approximately expressed by

$$F_i(s) = K U(s)$$

Where $U(s)$ is the Laplace transform of input voltage of the electrical heater band. Equation (3.6) becomes

$$E_0(s) = \frac{R R_1 K U(s)}{(R_1 + R) + R_1 R C s} \quad (3.7)$$

Considering the transport delay for heat transfer, we introduce dead time into equation (3.7).

$$E_0(s) = \frac{R R_1 K U(s)}{(R_1 + R) + R_1 R C s} e^{-\tau s} \quad (3.8)$$

Where τ is the dead time.

Thus, the thermal dynamic systems both for polymer hopper and polymer chamber can be approximately described by a first order process with dead time. Fig. 3.21 shows the temperature dynamic response of the polymer chamber heating process.

The control of a first order process can be simply implemented by a single-loop feedback control system with a controller such as PI, PID, or two position controller and a controllable power supply. Here two controllable power supplies with built in two position controllers were used to control the temperature of the polymer hopper and the polymer chamber respectively. Fig. 3.22 shows the block diagram of the control system.

Fig. 3.23 shows the closed loop dynamic response of the temperature measured from the thermocouple at position 2 (see Fig. 3.11). The

polymer in the melt hopper and melt chamber melted very quickly, but it took 80 minutes for the polymer to reach a uniform distribution and steady temperature level before the drawing process could be actually commenced. At steady state, the temperature was controlled within $\pm 3^{\circ}\text{C}$ of the set temperature. The setpoint of the temperature control system was given by the microcomputer.

Fig. 3.21 Step Response of the Polymer Melt Chamber
Heater Band Step Input 100 V

Fig. 3.23 Closed-loop Step Response of the Polymer Chamber Heating Process (Set Temperature 90°C)

3.5 - Wire Drawing Speed Control

As mentioned before, in the wire drawing process, it was required to adjust drawing speed over a given range with a desired accuracy and repeatability. A MC68000 microcomputer was used to implement the sampled data feedback control system. The schematic diagram of the microcomputer based system for controlling the speed of the hydraulic motor is shown in Fig. 3.24.

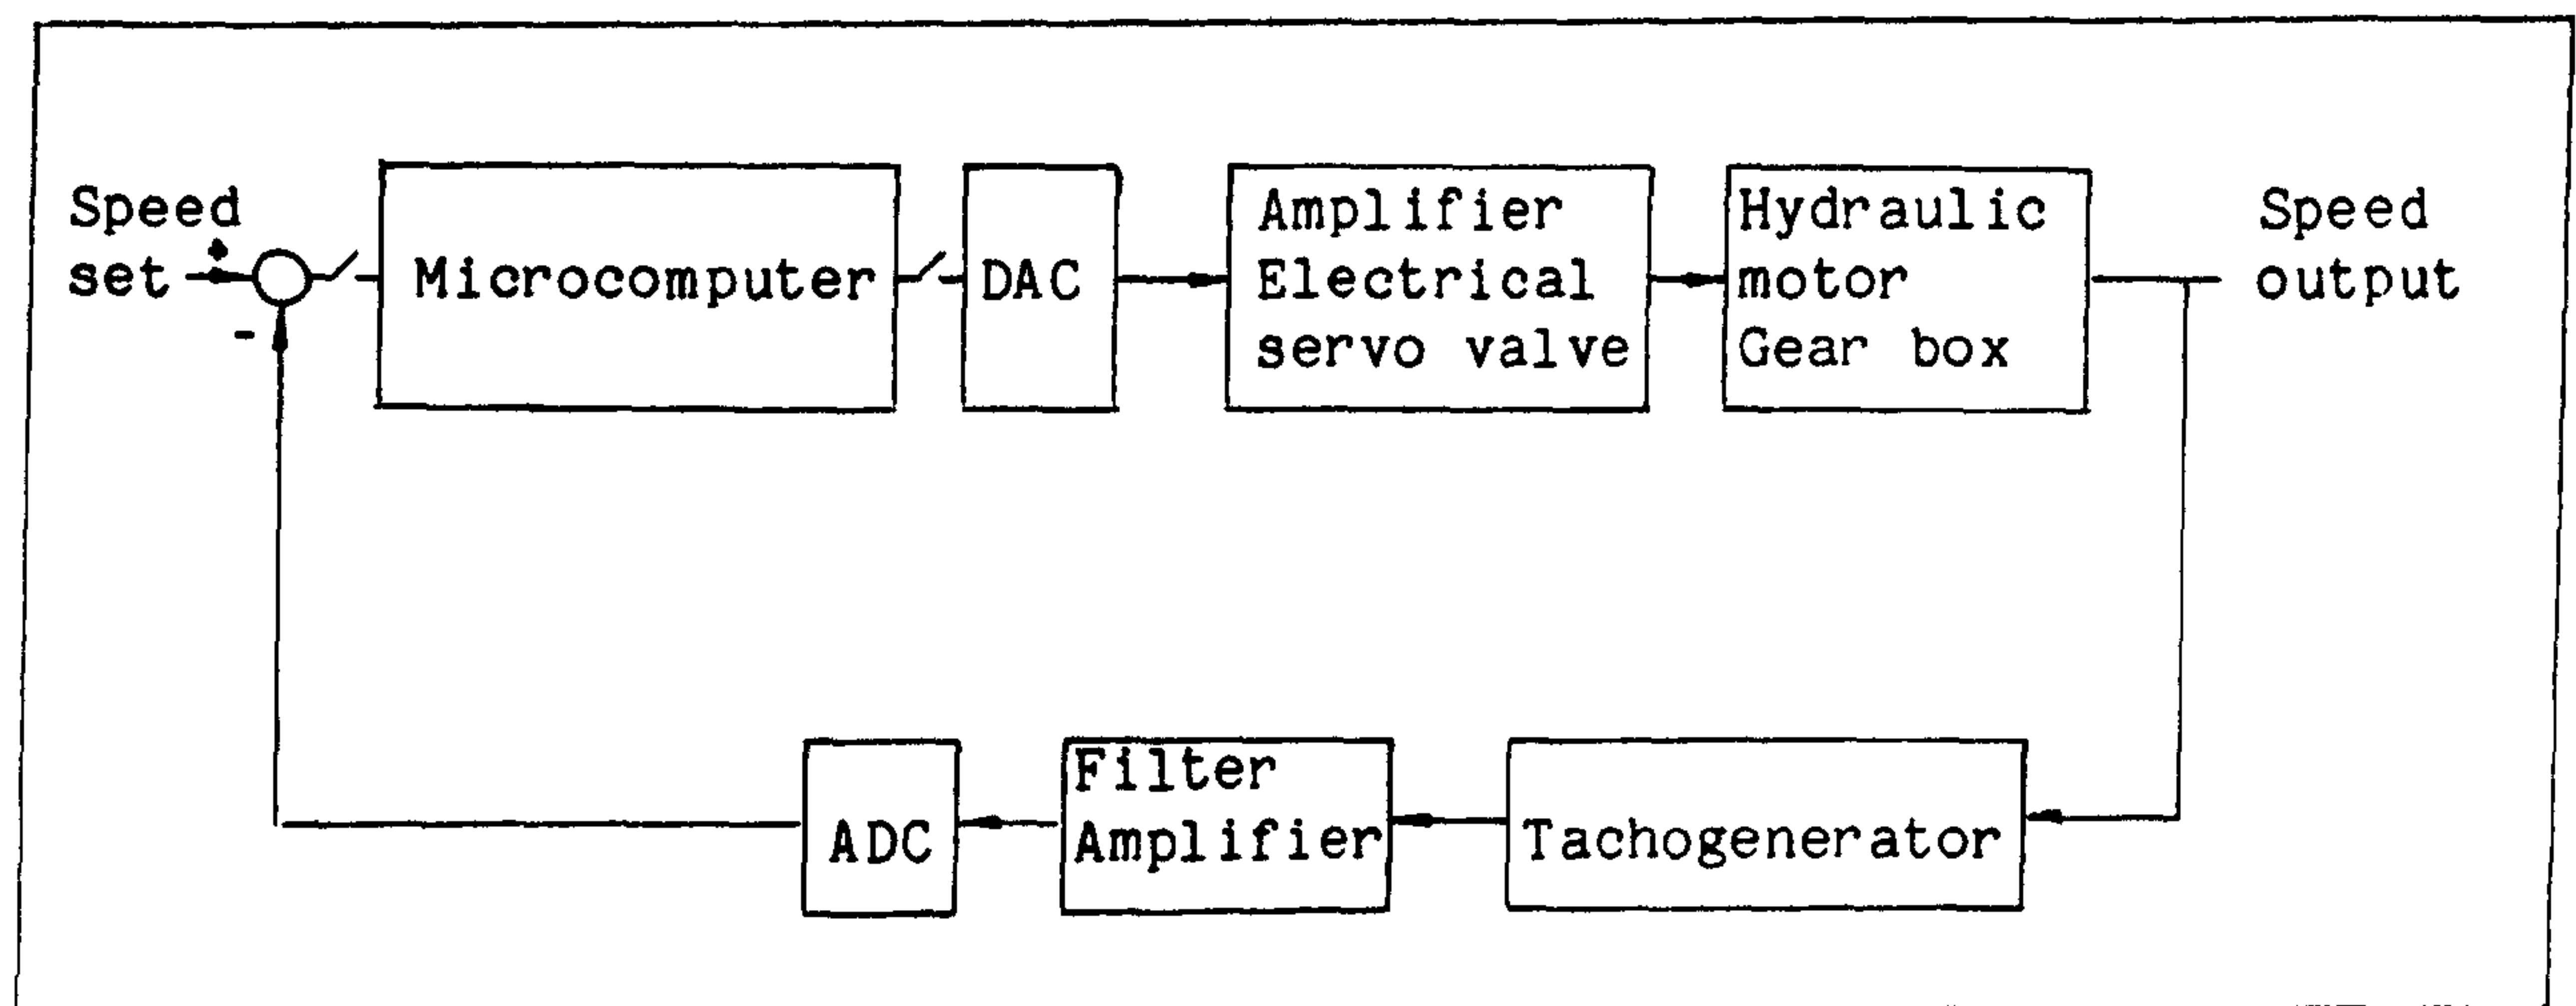

Fig. 3.24 Electro-Hydraulic Motor Control System

The system was not continuous, but measured and corrected the motor speed at discrete intervals. The order of the events in a complete control cycle was as follows.

- The actual speed measured from the tachogenerator, after being filtered and amplified, was converted into a digital number via the ADC.
- The digital feedback signal was compared with the setpoint to produce an error.
- The digital controller programmed in the computer generated a compensation signal.
- The compensation signal then was transmitted to the

electro-hydraulic servo valve via the DAC and the amplifier to vary the speed of the electro-hydraulic motor.

3.5.1 - Major Components of the Speed Control System

Electro-hydraulic Servo Valve

The servo valve is the main part of a hydraulic servo and its performance significantly affects the overall performance of the system. The servo valve in an electro-hydraulic system is essentially a component which produces hydraulic flow proportional to the electrical current applied. It is often the case that the transfer function of the servo valve can be described by a first order system [19], that is,

$$G_{sv}(s) = \frac{K_{sv}}{1 + T_{sv}s}$$

Hydraulic Motor

The function of the hydraulic motor in a hydraulic control system is to convert the hydraulic energy supplied by the pump into mechanical energy at its output shaft. The transfer function of a hydraulic motor is given by

$$G_M(s) = \frac{n(s)}{Y(s)} = \frac{K_m \omega_m^2}{s^2 + 2\zeta\omega_m s + \omega_m^2}$$

Where $n(s)$ is the velocity output

$Y(s)$ the flowrate of the valve

K_m the steady state gain

ω_m the natural frequency and ζ the damping ratio

Fig. 3.25 shows the step response of the hydraulic drive system (servo valve and motor), from which the system could be described by a second order system with $\omega_m = 36.6 \text{ rad s}^{-1}$ and $\zeta = 0.68$.

The rest of the components of the system include a tachogenerator with transfer function $K_g/(1 + T_g s)$, gear box with transfer function $3/29$, two amplifiers before the ADC and after the DAC respectively with transfer functions of K_1 and K_2 .

The gain of the process including the DAC, the amplifier, the hydraulic drive system, the tachogenerator and the ADC was set to 1. Fig. 3.26 shows the sampled data / output data of the microcomputer, from which it can be seen that the system has a good linearity.

Fig. 3.25 Step Response of the Hydraulic Drive System

Fig. 3.26 Microcomputer Sampled Data / Output Data

3.5.2 - Some Design Consideration

Sampling Period

The sampling period is an important design parameter for all sampled data control systems. There are several rules of thumb which can be used to determine the sampling period [20]. One is to relate the sampling period T to the desired rise time t_r , and t_r/T should be in the range of 2-4 in order to get a good servo performance of the closed-loop system. Alternatively assuming a sampling period of one tenth the sum of loop dead time plus first order time constant is often a good compromise. Some typical values of sampling periods obtained by experience can be easily found in published works [21]. For example, a typical speed control loop generally requires 0.01-0.02 second sampling period. Here, the sampling period for hydraulic motor speed control system was chosen in a range of 8 to 15 ms

Integral Windup (Reset Windup) and Its Correction

A digital integrator was incorporated in the forward path of the system to eliminate steady state error. With such a system, it was possible that the integrator could assume very large values if the control signal saturated when there was an error. This, referred to as the integral windup effect, could cause excessive overshooting and stability problems. Thus the controller had to be modified to give some degree of windup protection. This was accomplished by disabling the integrator whenever its output signal caused saturation in the actuator. In a digitally implemented controller such modification is easily available through software changes. In this case, the integrator was

disabled by the program when its output value reached \$F0 corresponding to the maximum open position of the electro-hydraulic valve, as shown in Fig. 3.27. Here, \$F0 is the saturation value, and whenever the controller output U reaches saturation value \$F0, the integrator input is set to zero.

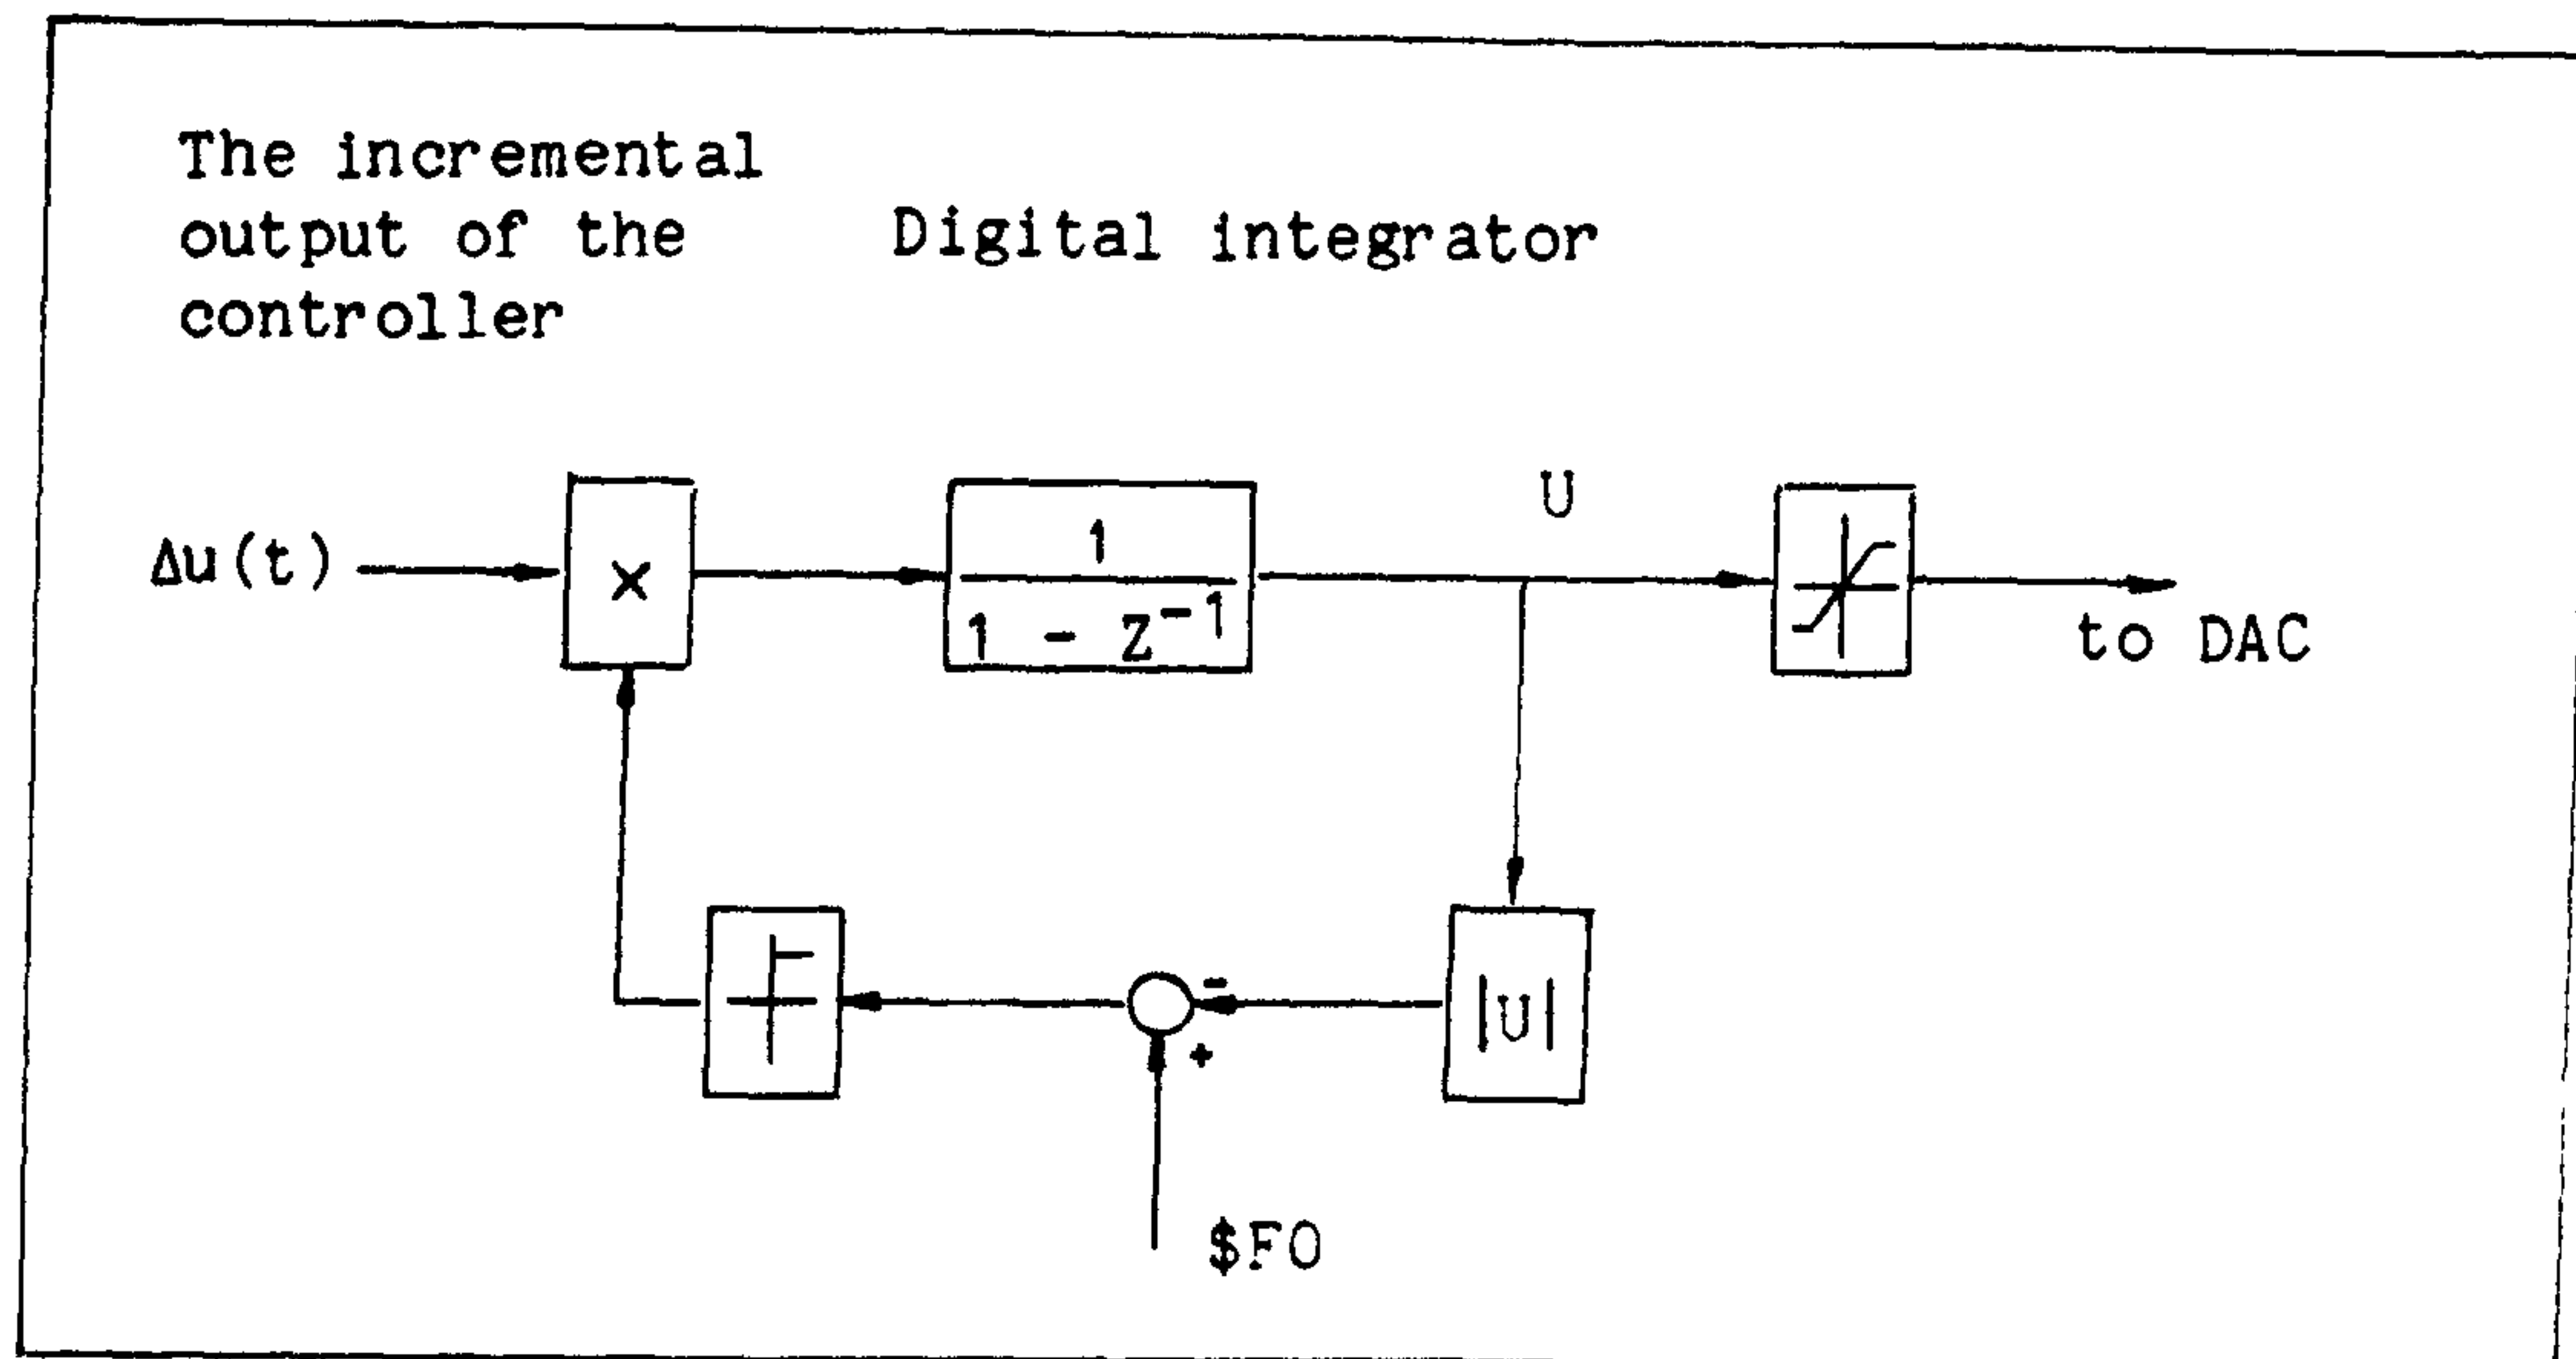

Fig. 3.27 Anti-Reset-Windup for Integrator

The program executing this function goes as follows

* Anti-integral windup, the initial value of the integrator is in the
 * memory location of \$U1, incremental output in D4, \$F0 the saturation
 * level.

```
Star:  ADD  $U1,  D4      ; Integrating

Star3:
```

Filtering

The analog feedback signal coming from the tachogenerator contained wide bandwidth noise of relatively large magnitude due to serious commutation problems. A simple analogue RC low-pass filter, as shown in Fig. 3.17, $1/(1+T_f s)$, with T_f chosen to be 0.04 second, had to be used to attenuate sufficiently the noise component. However, its dynamics somewhat degraded the response of the control system. An additional stage of digital low-pass filter (after the sampler) was also programmed into the microcomputer, in order to improve the performance of the system. The digital filter given by equation (3.9) is a version of a simple first order lag, where T is the sampling period, τ is the time constant of the first order lag, and τ can be simply chosen to be about $T/2$ [21].

$$Y(n) = \frac{1}{Q} X(n) + \left(1 - \frac{1}{Q}\right) Y(n-1) \quad (3.9)$$

where $Q = \frac{1}{1 - e^{-T/\tau}}$

Accuracy and Word Size

The component introducing the largest error into the control system was the tachogenerator with accuracy of about ± 1 percent. Thus the whole accuracy of the control system could not be better than ± 1 percent. An 8 bit ADC giving a resolution of 0.4 percent was used, and 16 bit or 32 bit word length was employed to represent a number and to handle the mathematical operation. However, the final words were truncated to 8 bits, the DAC size. A hand micrometer was used to measure the wire

diameter and ± 0.005 mm error was allowed in the reading, therefore ± 2 percent error was estimated in the reduction in area of the wire. The maximum error of the whole speed control system was designed within ± 2 percent, which only caused less than ± 1 percent error in the reduction in area of the wire, so the accuracy of the control system could meet the demand of the allowed error in the reduction in area of within ± 2 percent.

3.5.3 - Analysis of the Control System

Fig. 3.28 shows the open loop step response of the process including the amplifier, the servo valve, the hydraulic motor, the gear box and the tachogenerator, from which the transfer function of the process can be approximately given by

$$G(s) = \frac{e^{-0.012s}}{(0.06s + 1)(0.01s + 1)}$$

and

$$G(z^{-1}) = \frac{z^{-2}(0.088 + 0.043z^{-1})}{1 - 1.11z^{-1} + 0.243z^{-2}}$$

with sampling period 0.012 second.

The Z transfer function of the digital PID controller employed in the closed loop is given by

$$G(z^{-1}) = \frac{g_0 + g_1z^{-1} + g_2z^{-2}}{(h_0 + h_1z^{-1})(1 - z^{-1})}$$

Where $h_0 = 0.3$, $h_1 = 0.19$, $g_0 = 1.33$, $g_1 = -1.37$, and $g_2 = 0.125$. The design of the digital PID controller will be described in chapter 4.

Fig. 3.29 shows the block diagram of the speed control system.

Fig. 3.28 Step Response of the Drive System

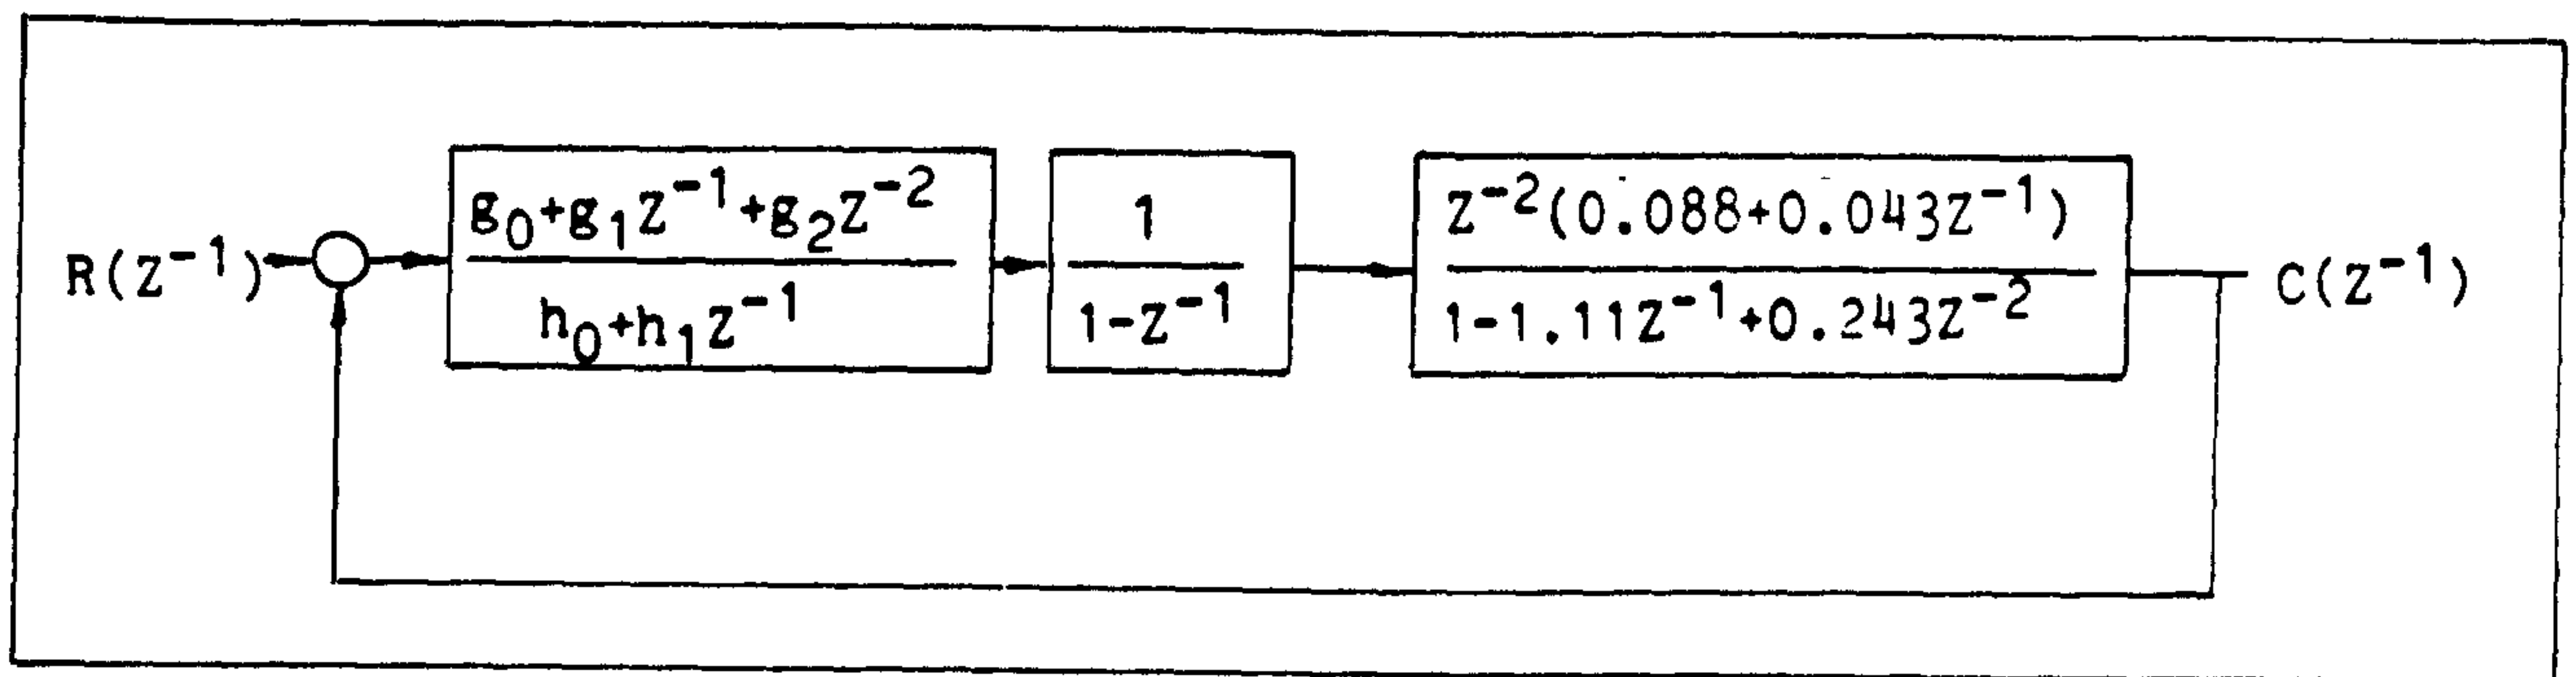

Fig. 3.29 Block Diagram of the Speed Control System

The stability of the system can be determined from the locations of the roots of the characteristic equation given by

$$30x^5 - 44.3x^4 + 12.2x^3 + 12.02x^2 - 9.4x + 0.54 = 0$$

from which the roots are found to be 0.94, -0.596, 0.0624 and $0.53 \pm 0.95j$. Thus any root of the characteristic equation has a magnitude less than unity, and the system is stable. Fig. 3.30 shows the the closed loop step response of the speed control system.

Fig. 3.30 a) Closed-Loop Step Response of the Speed Control System
b) Closed-Loop Response of the Speed Control System with Same Step Input Applied, via a Digital Filter

3.6 - Software Configuration

Based on the experimental results, polymer WVG 23 at 110°C set temperature, polymer ELVAX 650 at 150°C set temperature and polymer Nylon 6 at 260°C set temperature were chosen as pressure media for the dieless wire drawing.

3.6.1 - Producing Wire of a Uniform Diameter

Before the drawing process is started, the specification is input by following a prompt on the microcomputer screen: " Input the polymer number (1-WVG, 2-ELVAX, 3-NYLON) in memory location of \$2000, the desired value of PRA in memory location \$2002, then run the program starting address \$2100 ".

Depending upon the input data, the microcomputer determined the temperature and the drawing speed setpoints via built-in look-up tables. The look-up tables were based on the experimental results, for example, as shown in Fig. 3.31, in which the incremental zone of the curve was portioned into 5 segments and each nonlinear segment was replaced by a linear approximation. Thus, only the values of the six break points needed to be stored in the microcomputer, and the speed setpoint corresponding to a given PRA could be calculated from a linear equation. A simplified flowchart as shown in Fig. 3.32 can easily explain the nature of the program.

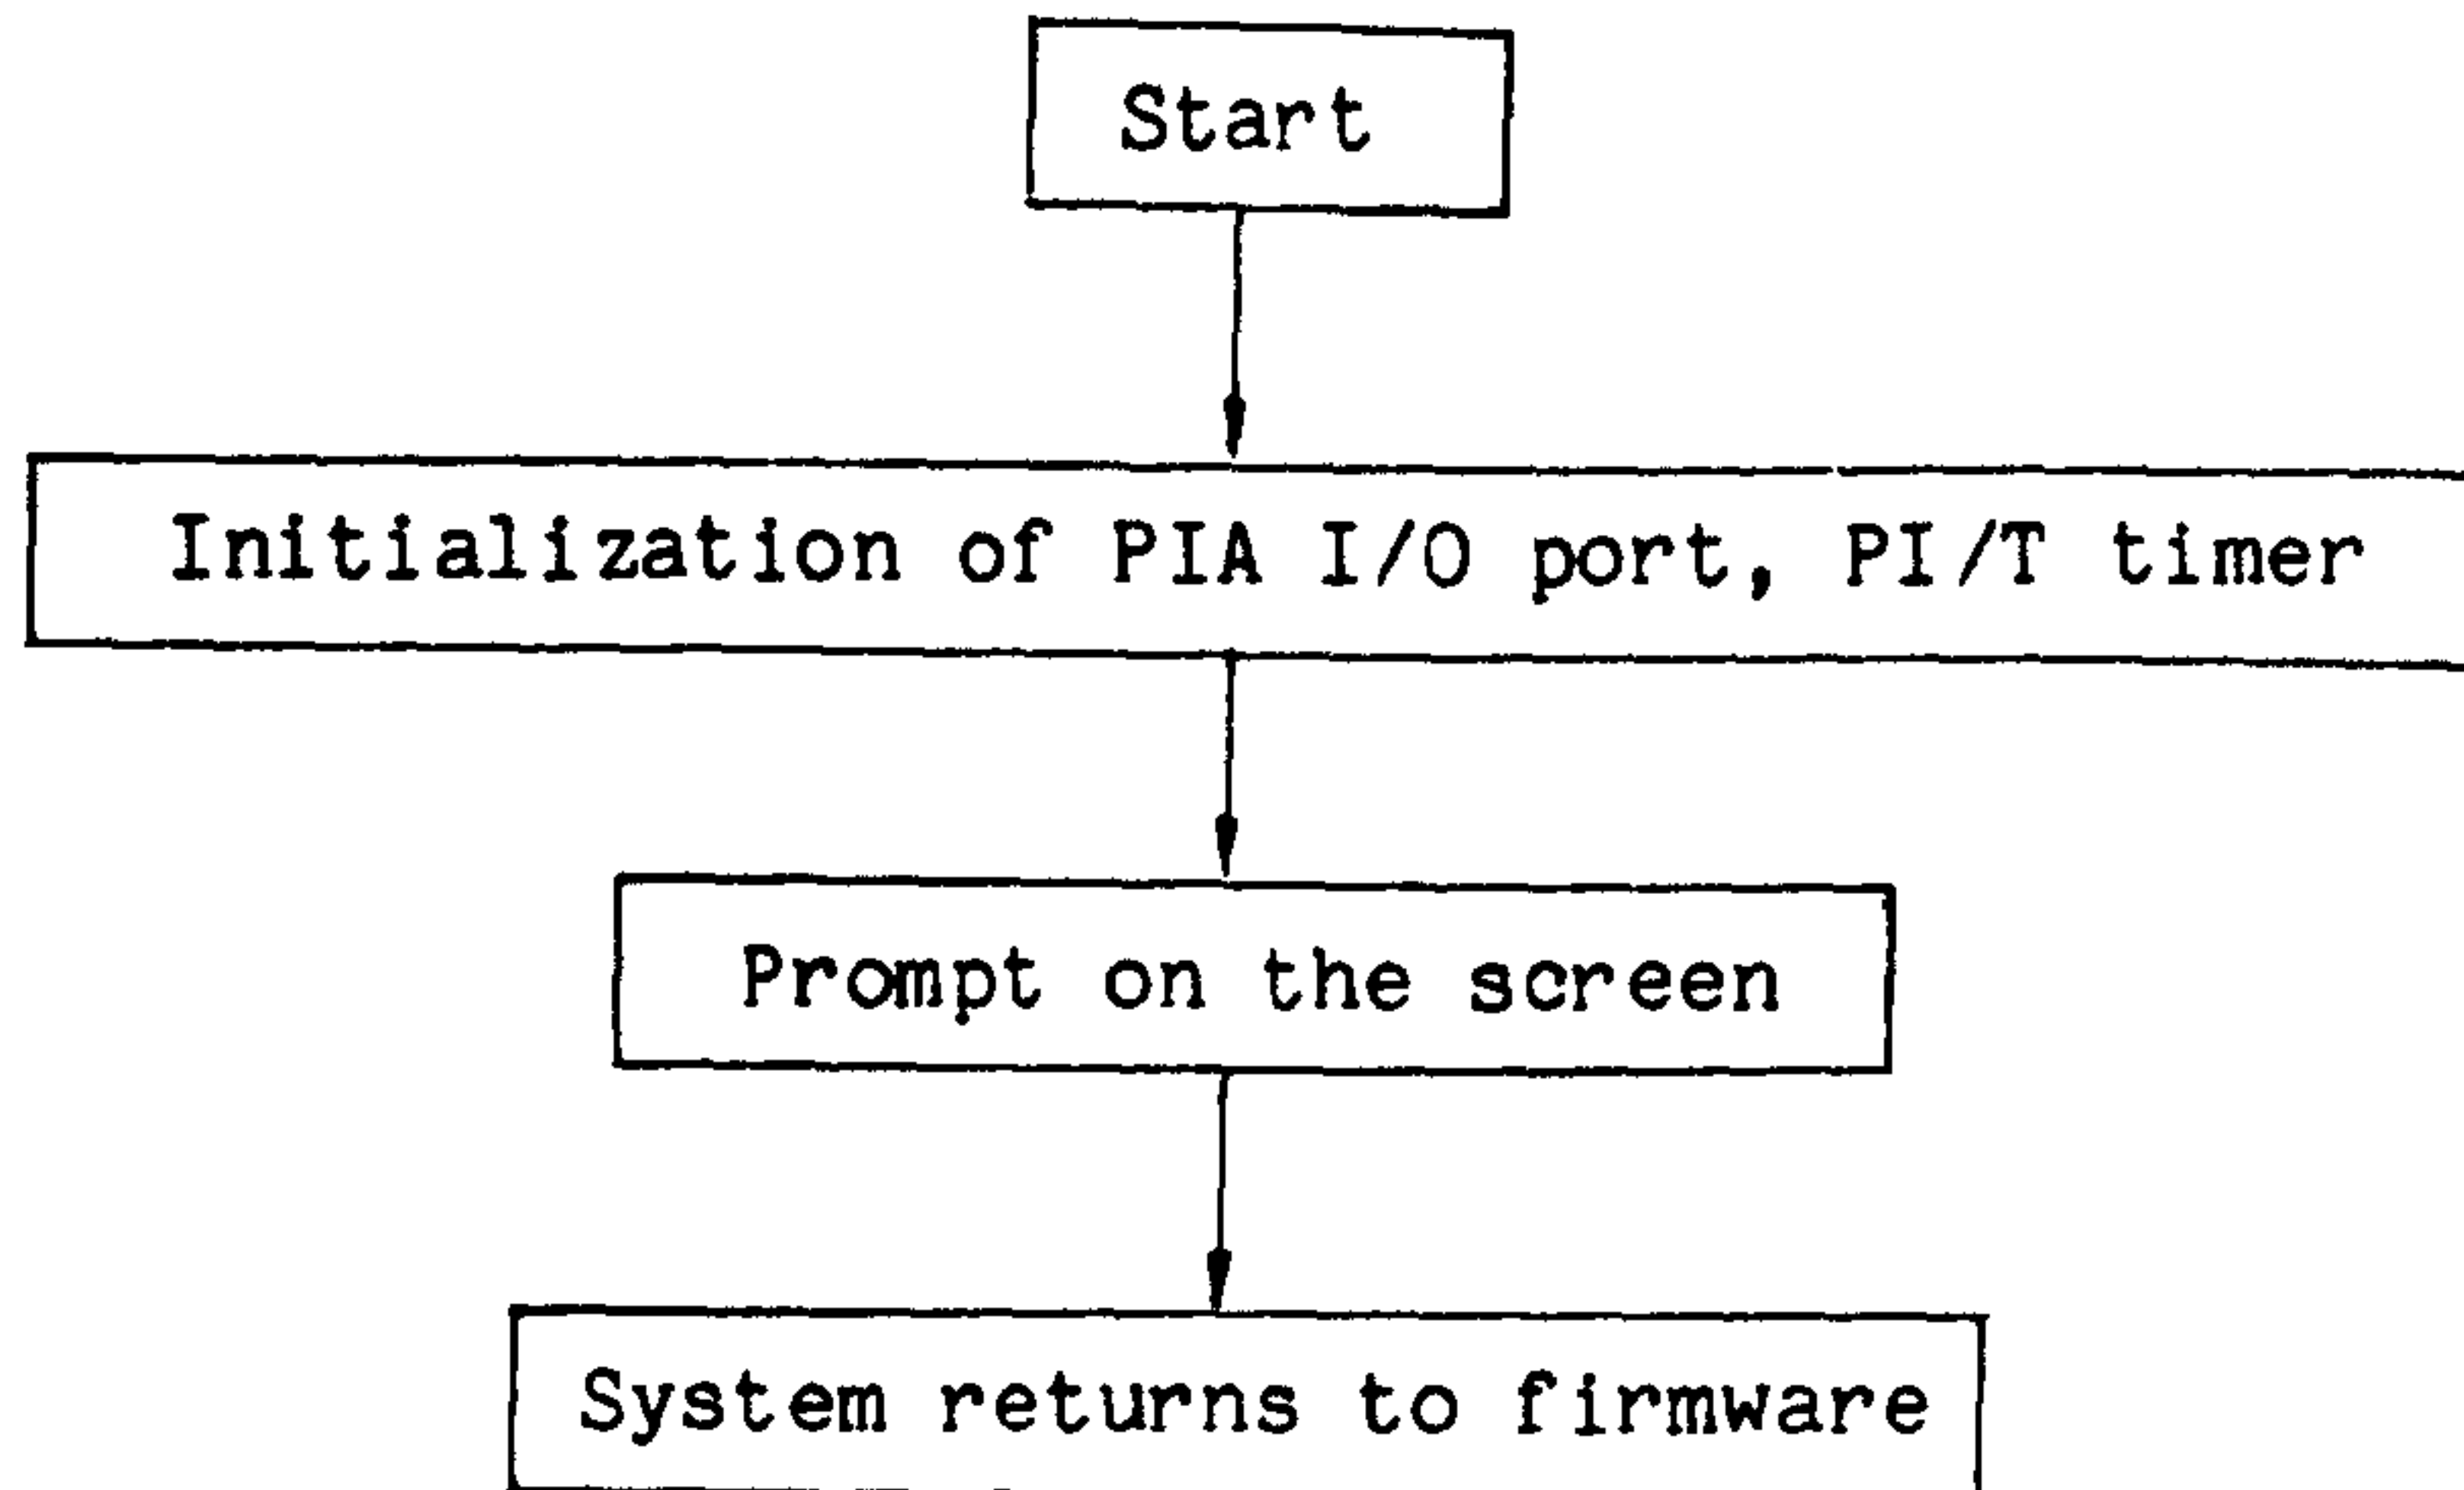

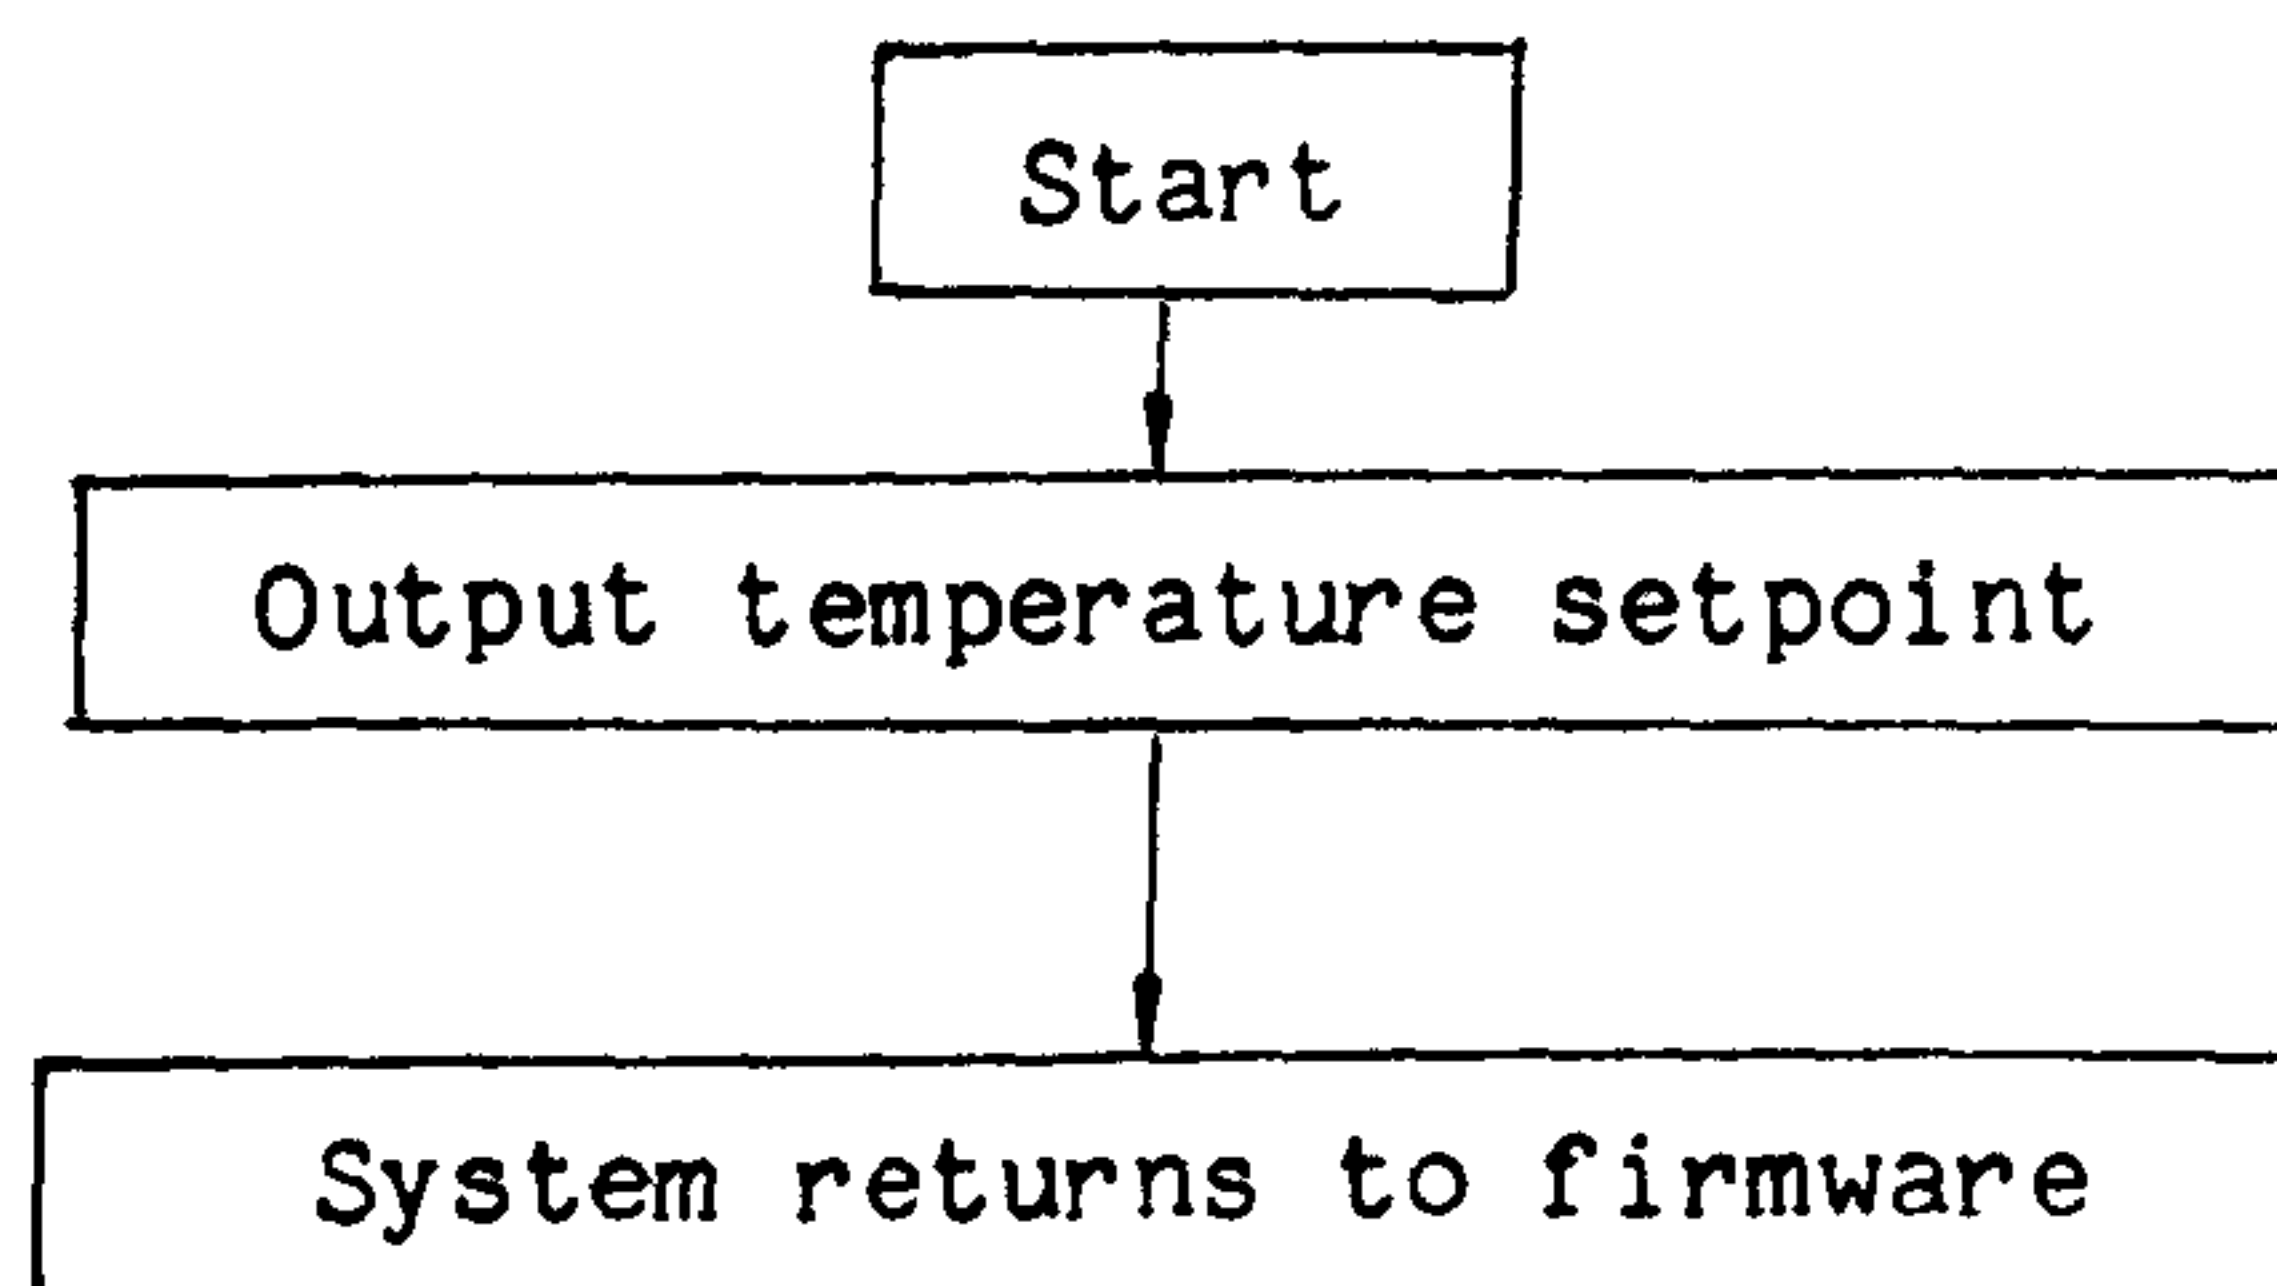

Fig. 3.31 The Percentage Reduction in Area

Input the value of the desired PRA and the polymer number via the keyboard.

Wait for the increase in temperature and the uniform distribution of the temperature within the DRU.

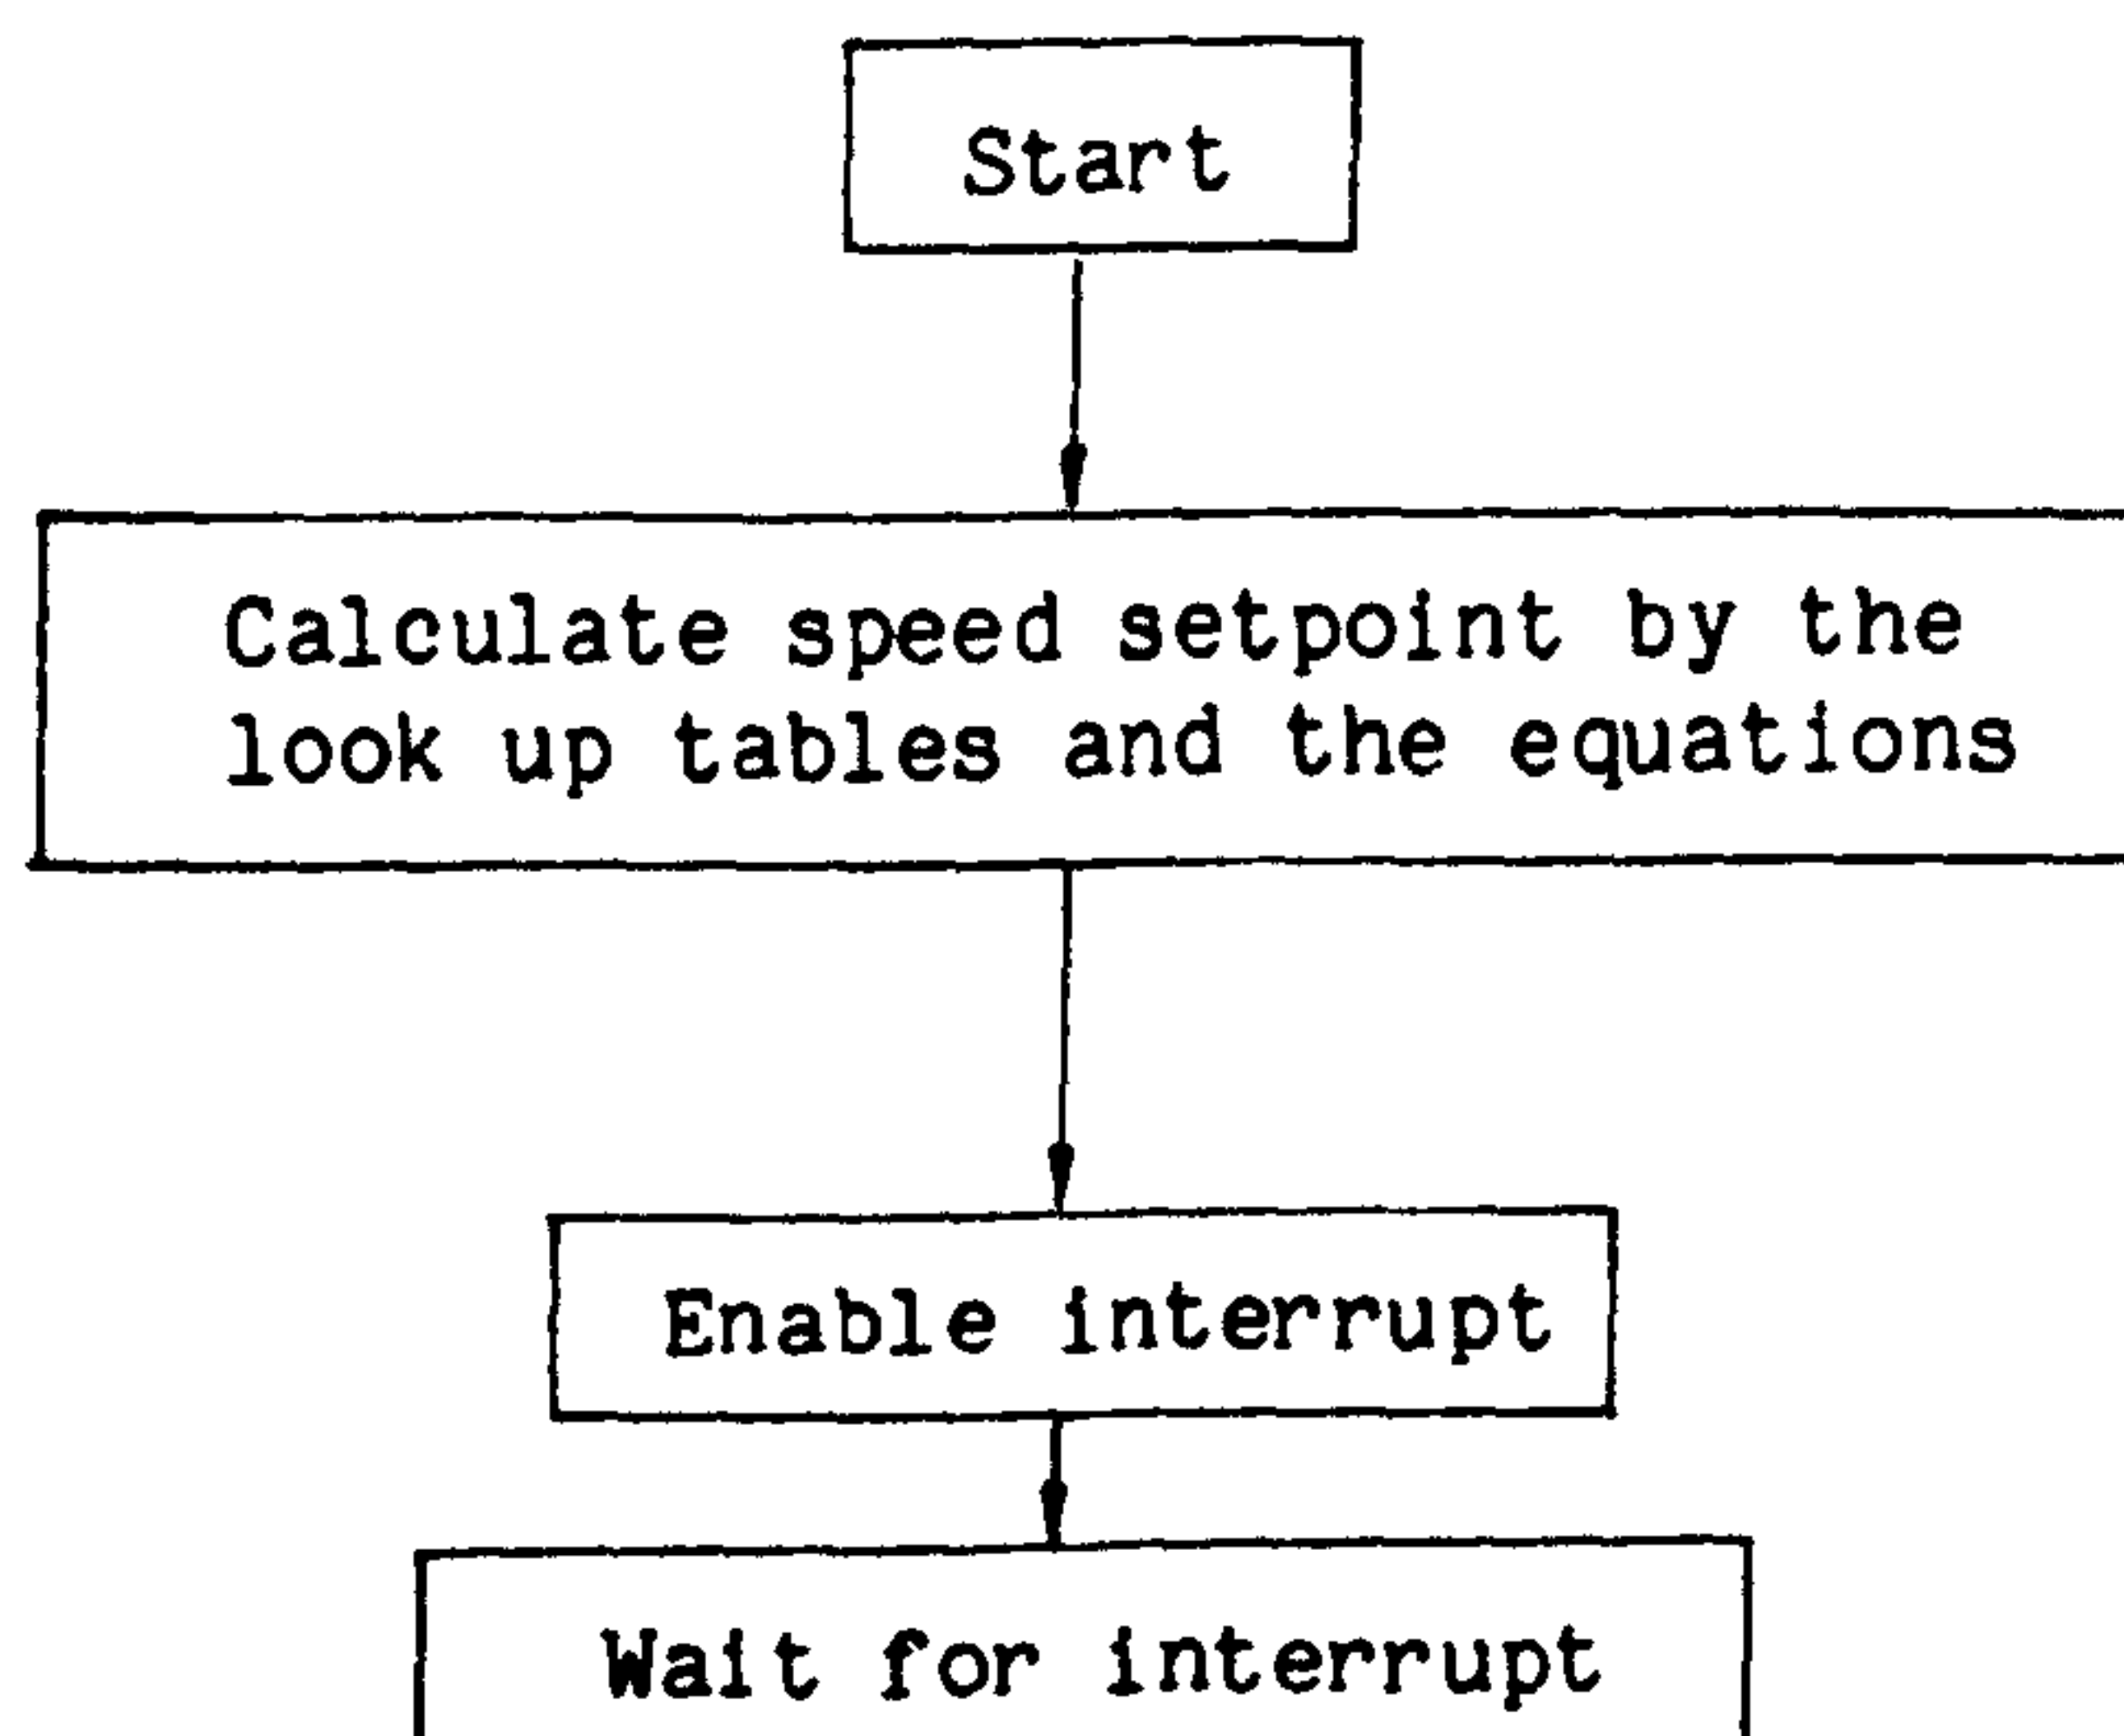

Fig. 3.32 Flowchart of Drawing Wire of a Uniform Diameter

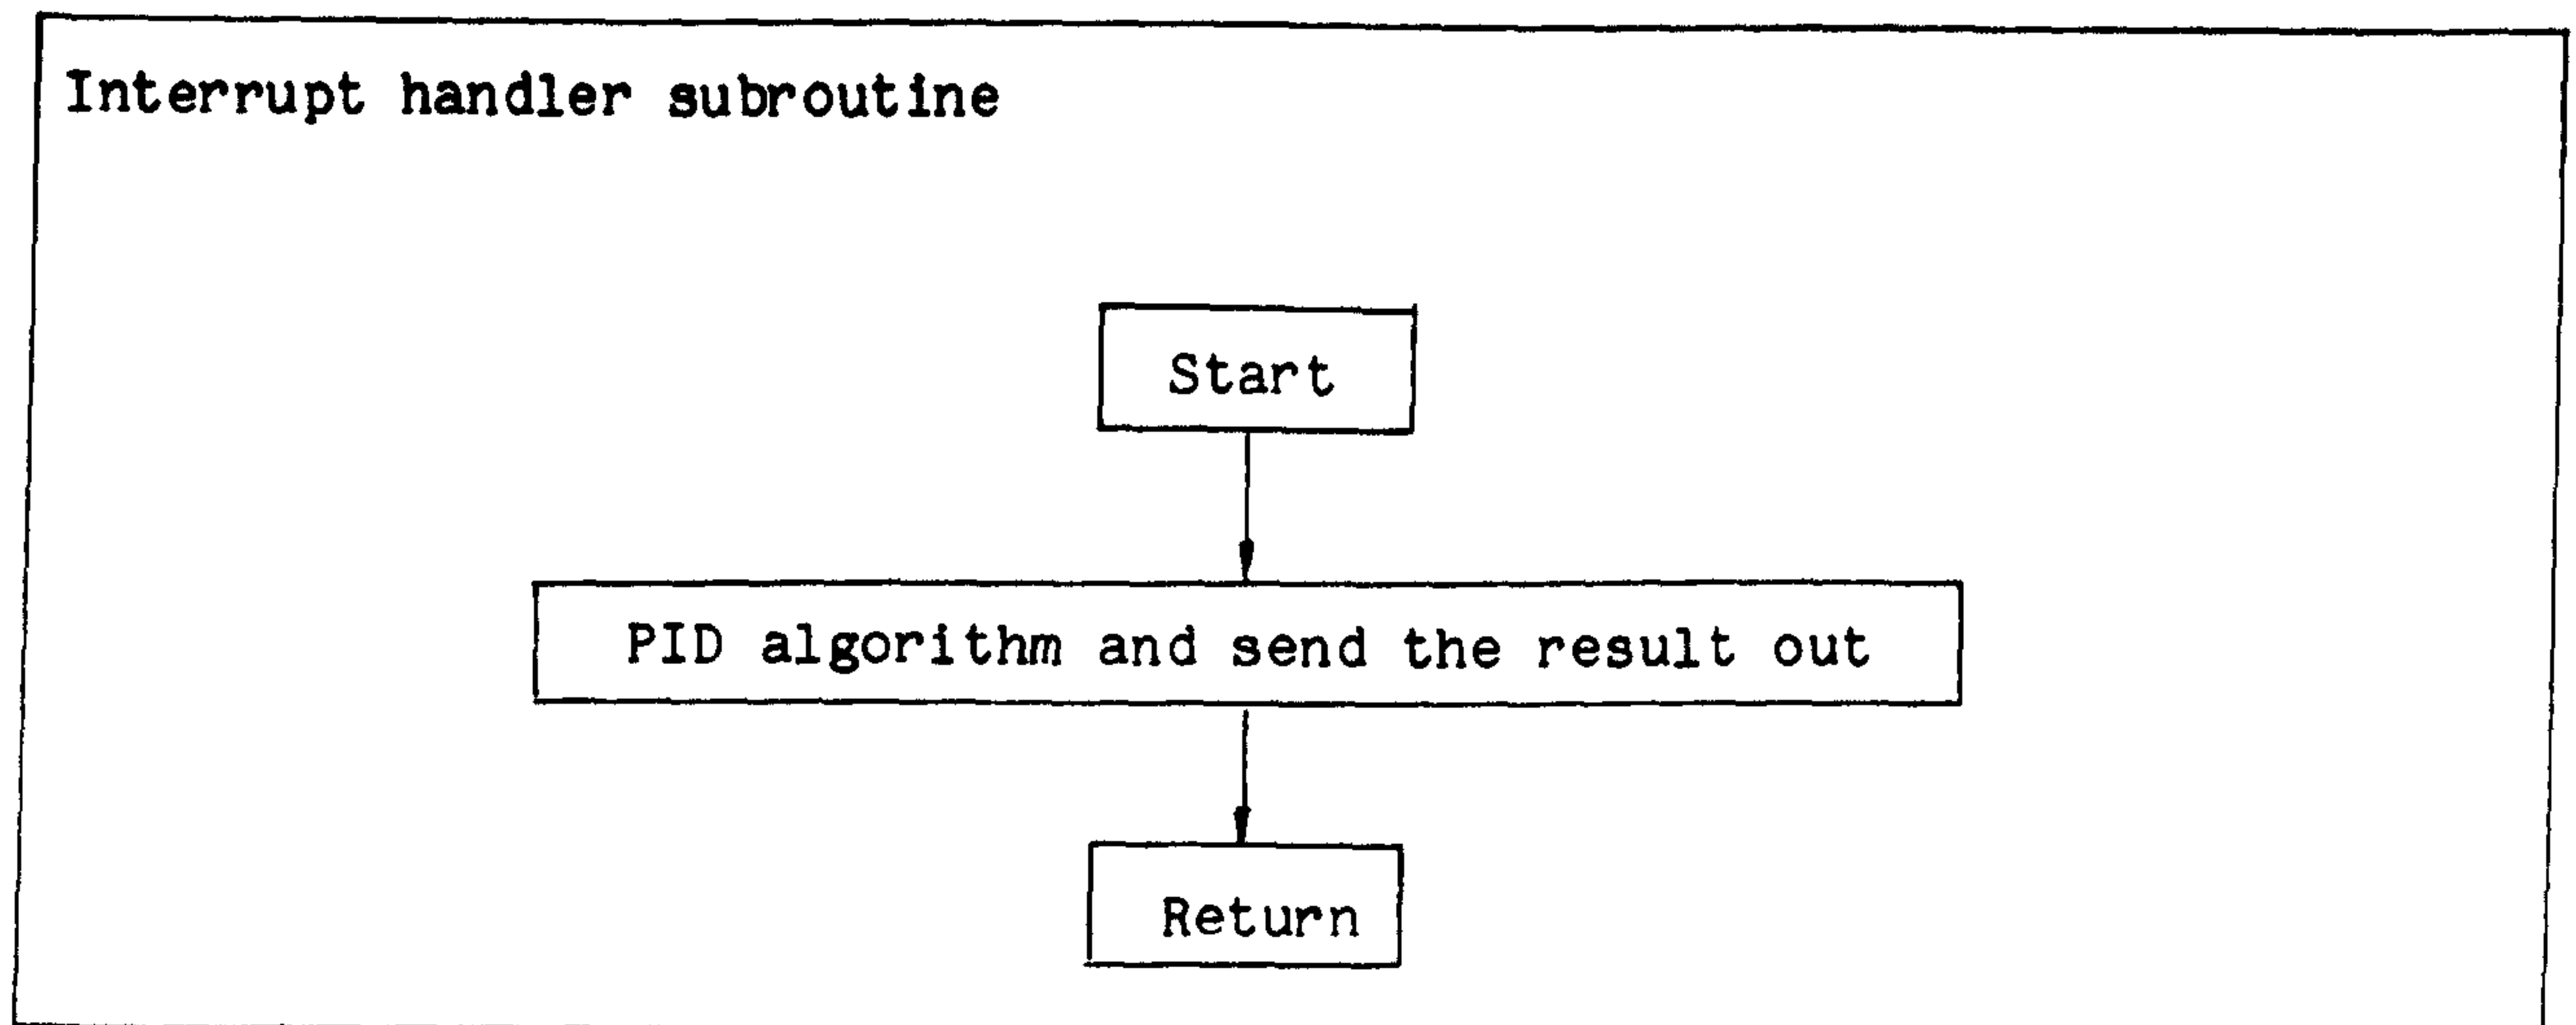

Fig. 3.32 Flowchart of Drawing Wire of a Uniform Diameter

After the microcomputer had displayed the prompt on the screen, instructions in the user program returned control of the system to the firmware. Data could then be input via the keyboard, and the user program was restarted by the operator. After the temperature reached a steady state (usually 80 minutes), the wire drawing process was initiated by the program. The program listing is given in Appendix 5.

3.6.2 - Producing Tapered Wire

The lack of a PRA transducer in the control system caused some complexity in drawing tapered wires. Here only the linear portion of the PRA curve was used to produce tapered wire. Because of its good linearity properties (as shown in Fig. 3.6), polymer ELVAX at 150°C was chosen as the best pressure medium to produce tapered wires. The drawing speed was controlled to increase with a properly selected rate to produce the wire with a uniform change in area along the length of the wire. The specifications of the required tapered wire were PRA1 and PRA2, corresponding to the values of the PRA at the large and the small end of the wire respectively, and L, the desired length of the tapered

wire. From Fig. 3.6, the speeds V_1 and V_2 corresponding to the given PRA1 and PRA2 respectively could be calculated by equation (3.10).

$$V = \frac{(PRA - 0.045)}{0.1584} \quad (3.10)$$

As mentioned before, the speed control system facilitated a drawing speed variable between 0 and 1.3 ms^{-1} . For 8-bit length of word, the step size of the speed was given by

$$1_{1sb} = \frac{1.3}{255} = 0.0051 \text{ ms}^{-1}$$

Thus the numbers N_1 and N_2 corresponding to V_1 and V_2 respectively were

$$N_1 = \frac{V_1}{1_{1sb}}$$

and

$$N_2 = \frac{V_2}{1_{1sb}}$$

The drawn length l in every speed step should be equal and was given by

$$l = \frac{L}{(N_2 - N_1)}$$

Interrupt with interval T was used to count the time passed and so at any speed step N , the drawing time n in terms of number of the interrupt interval was given by

$$\begin{aligned} n &= \frac{1}{1_{1sb} N T} \\ &= \frac{L}{(N_2 - N_1) 1_{1sb} T N} \end{aligned}$$

The drawing process started at the lowest speed N_1 with drawing time $n_1 = c/N_1$, where $c = L / ((N_2 - N_1) 1_{1sb} T N)$. After that, the microcomputer increased the speed step by 1, i.e., N_1+1 , and calculated the drawing time $n_2 = c/(N_1+1)$, this sequence continued step by step until the final speed step N_2 was completed and the process stopped.

During the above procedure, the microcomputer not only calculated

the drawing speed and time, but executed the PID action simultaneously to ensure that the actual drawing speed would follow the speed setpoint.

Fig. 3.33 shows the flowchart of the program. The first step to start a drawing process was to input the specifications of the wire. Then the microcomputer calculated the starting speed step N_1 , the final speed N_2 and the constant c , initialized the I/O ports and the timer, and started the drawing process. The interrupt handler routine decided whether the PID action was to be executed and the speed step was to be increased. Having finished the drawing process, the microcomputer turned to execute an alternative interrupt handler routine which would enable hydraulic motor to stop with a somewhat slower rate. The program listing for the tapered wire drawing is given in Appendix 6.

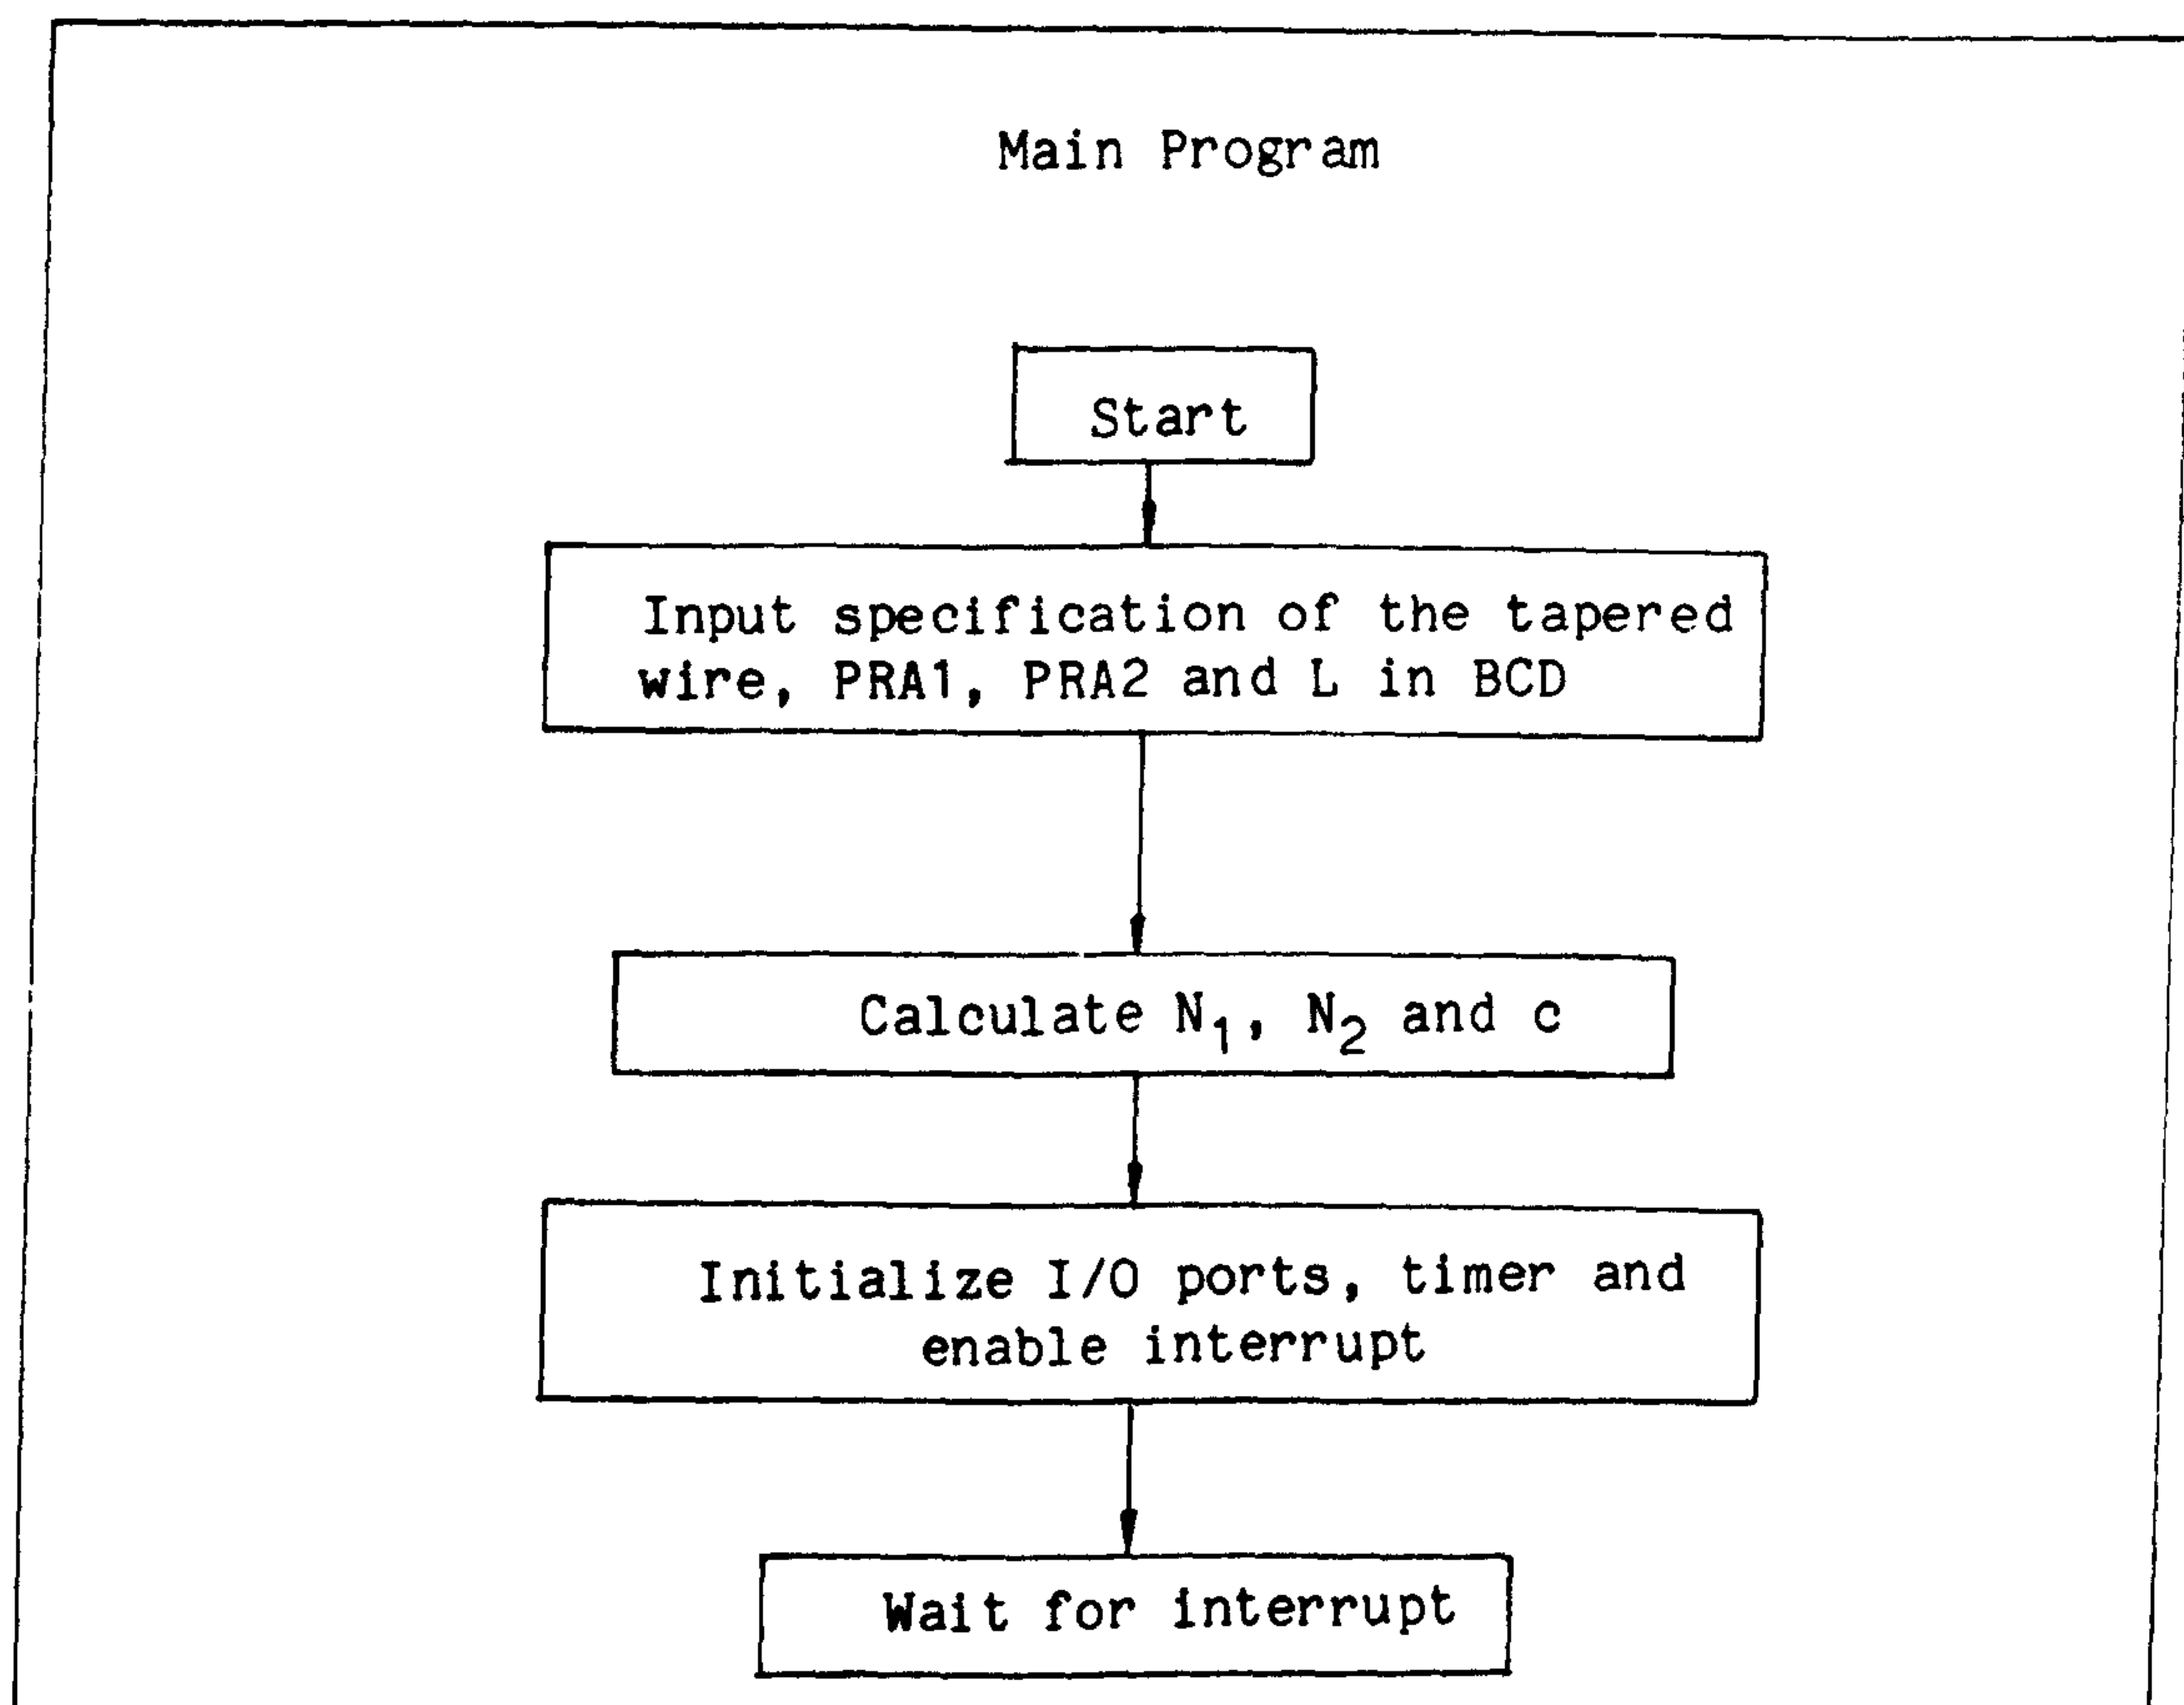

Fig. 3.33 Flowchart of the Tapered Wire Drawing Program

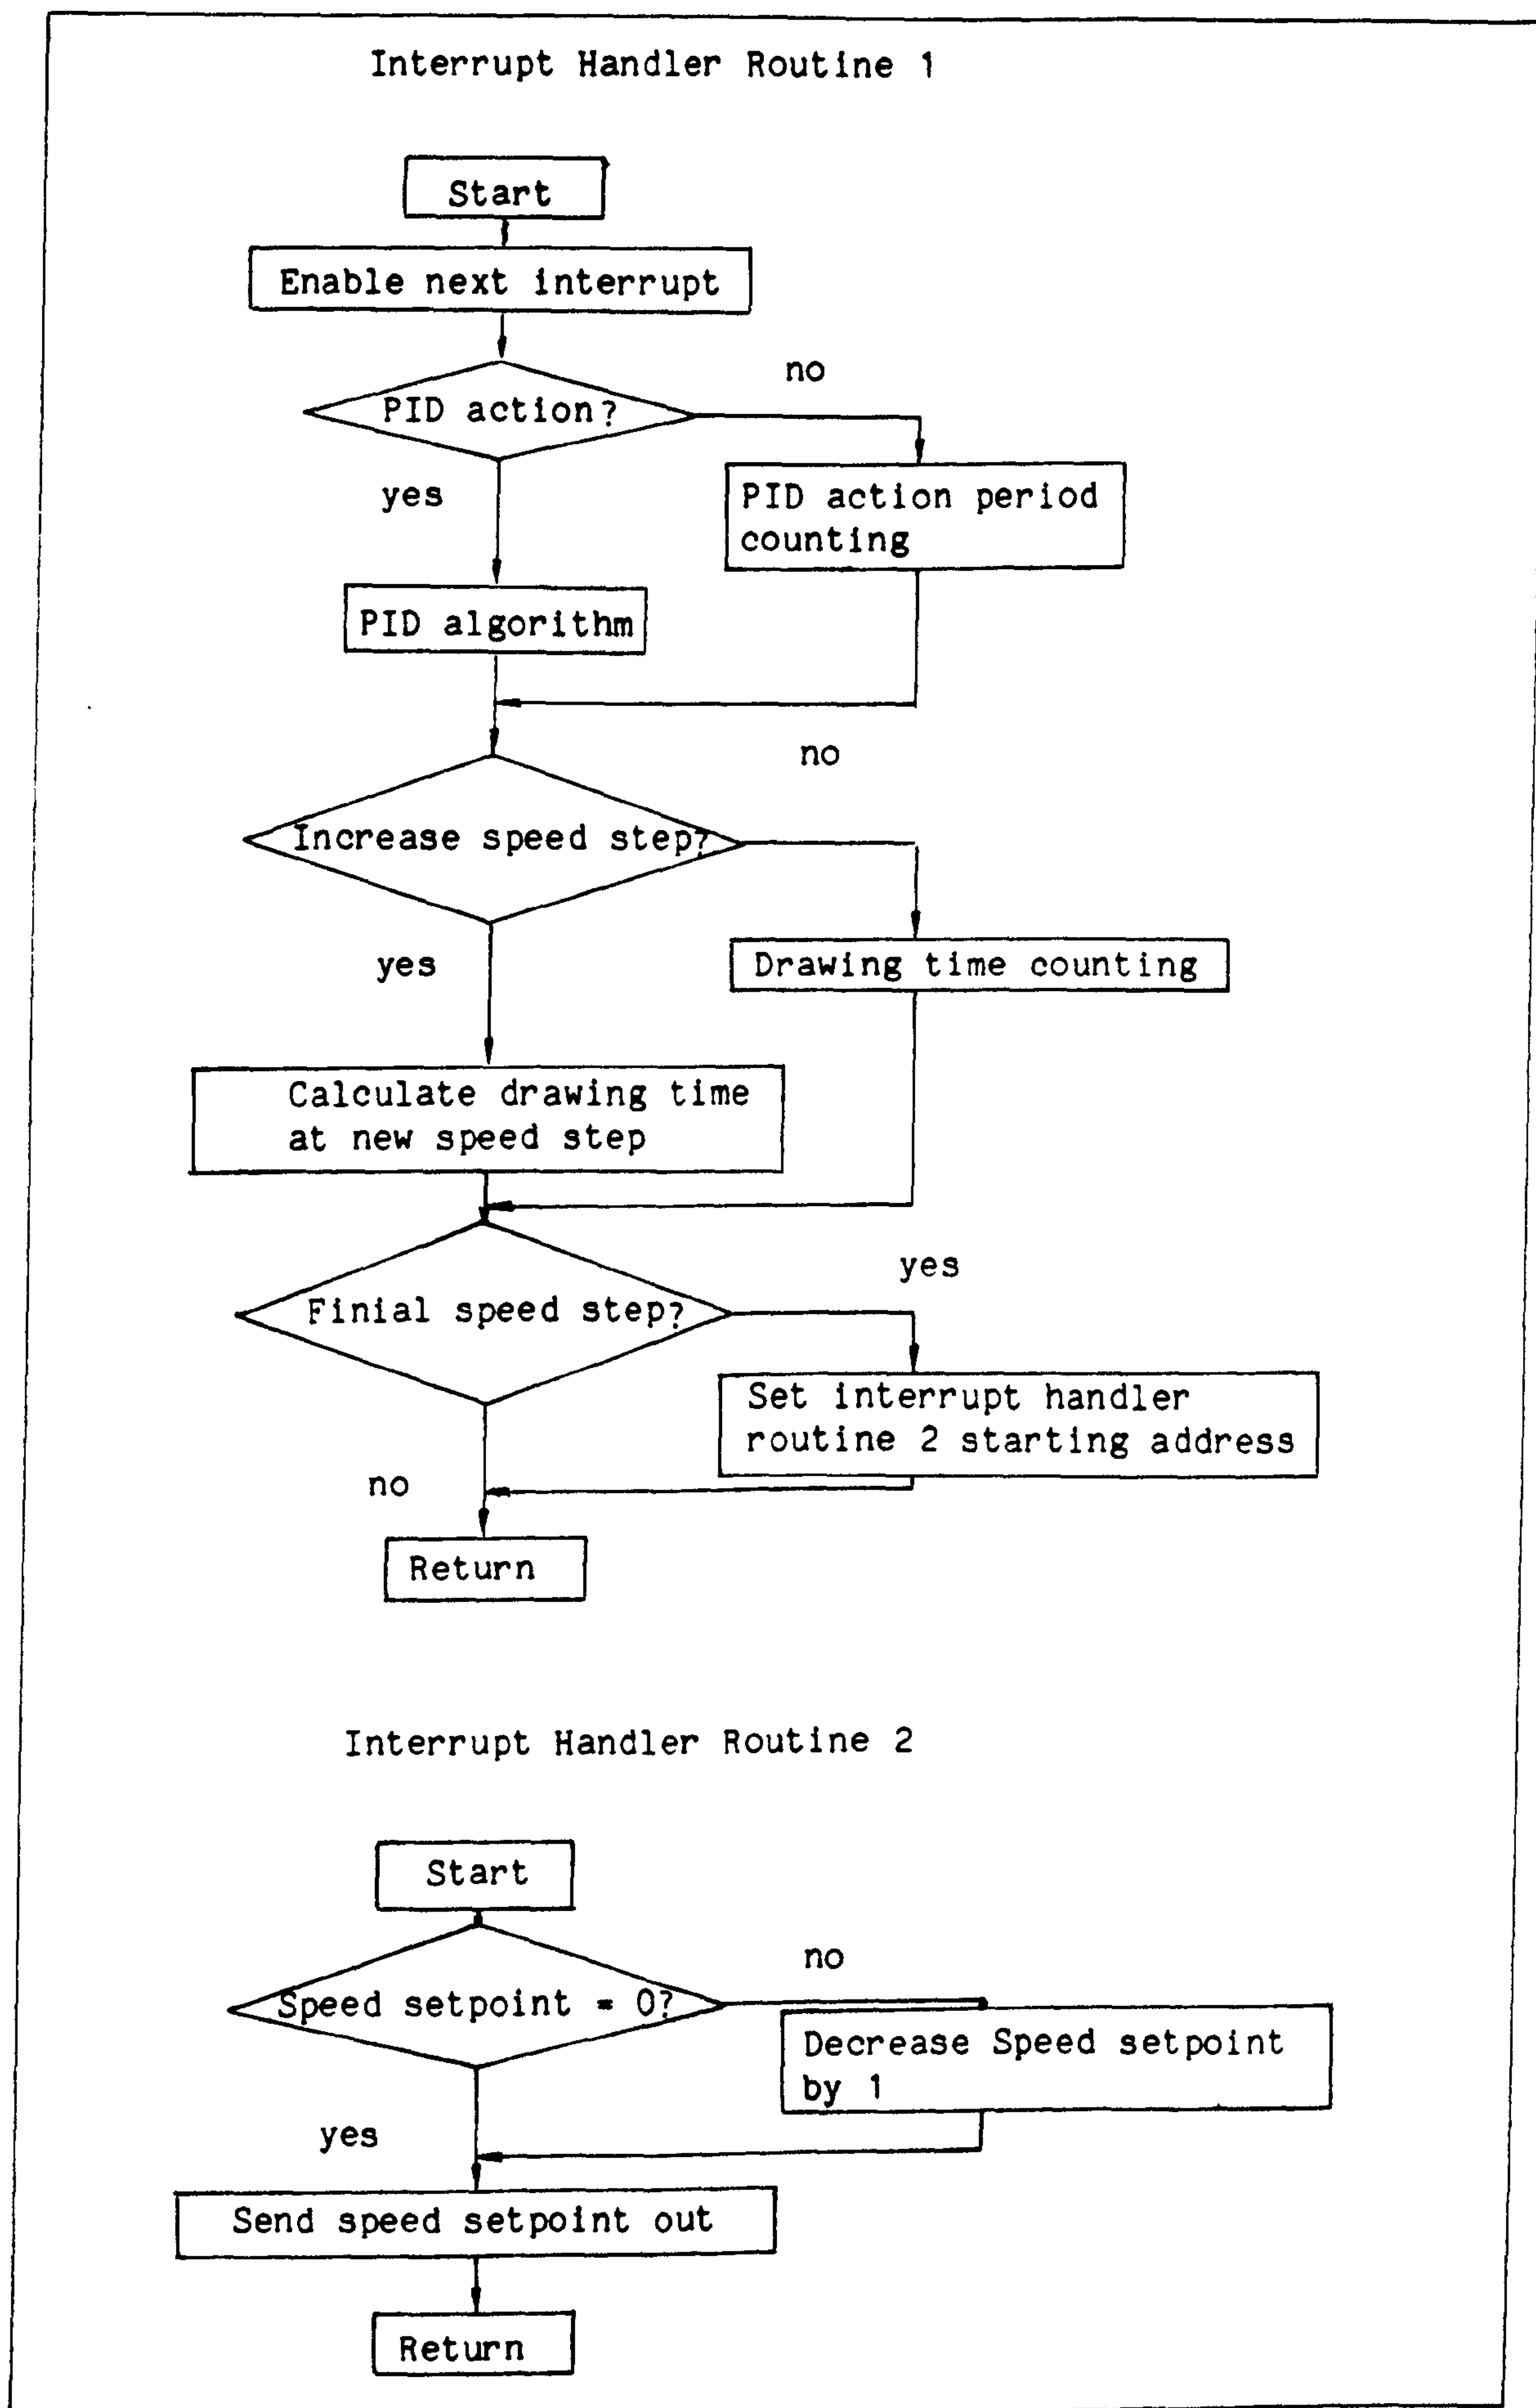

Fig. 3.33 Flowchart of the Tapered Wire Drawing Program

3.7 - The PRA Transducer

To implement a closed-loop control system in which the controlled variable is the PRA of the wire and the manipulated variable is the drawing speed, a transducer is needed to make the information available from a measurement of the PRA. In closed-loop control, since the accuracy of the system output, i.e., the quality of the product will be decided by the accuracy with which the measurement is performed, emphasis must be given to the development of a new measuring method with desired accuracy.

As mentioned before, when the wire is pulled through the DRU, there is a polymer coating on the surface of the wire. Therefore the diameter of the wire can not be measured with a conventional measuring method. A method was developed with which the reduction in area of the wire could be measured. The new design utilises two rotary shaft encoders, one on each side of the DRU, as shown in Fig. 3.34a. The encoders are driven by the wire being drawn via friction wheels mounted on the encoder shafts. The encoders generate two trains of pulses whose frequencies are proportional to the speeds of the wire at the inlet and exit of the DRU respectively. The flow continuity law gives

$$V_1 S_1 = V_2 S_2$$

Where V_1 - the speed of the wire at the inlet of the DRU

V_2 - the speed of the wire at the exit of the DRU

S_1 - the cross section area of the wire before the DRU

S_2 - the cross section area of the wire after the DRU

So the reduction in area of the wire is given by

$$\text{PRA} = (1 - S_2 / S_1) * 100$$

$$= (1 - V_1 / V_2) * 100$$

By measuring the speeds of V_1 and V_2 , the microcomputer can easily calculate the PRA on line.

3.7.1 - Hardware

Fig. 3.34a shows the schematic diagram of the transducer and Plate 4 shows its arrangement on the bench. The major components of the transducer are described as follows.

The rotary shaft encoder (Type EA6-CW100) used was a subminiature optical incremental encoder with resolution of 100 pulses per revolution and bi-directional output. It provided a train of pulses with a frequency proportional to the angular velocity

A Schmitt trigger (HEF 4093B) used to shape the pulse train received from the encoder to produce a clean square wave at the output of the pulse shaper. The square wave was fed to a $\div 4$ frequency divider implemented on a 7-bit binary counter (HEF 4024B) as shown in Fig. 3.35. This provided averaging of the indicated speed over two encoder pulses.

To reduce the influence of the stray noise on the signal from the encoder, a 12 V power supply was required for the encoders. The outputs of the dividers, however, could not be directly connected to the MC6840, because the MC6840 required a TTL voltage. Hence optoisolators (Quadtransistor 307-064) were interposed between the pulse generating circuit and the MC6840. In addition to the function of voltage matching, optoisolators also eliminated the influence of the noise.

The MC6840 was used to count the pulses from the encoders. The MC6840 was a programmable subsystem component of the MC6800 family designed to provide variable system time intervals.

The MC6840 has three 16-bit binary counters (timer 1-3), three corresponding control registers (CR 1-3), and a status register (SR). These counters are under software control and may be used to cause system interrupts or generate output signals. The MC6840 may be utilized for such tasks as frequency measurements, event counting, interval

measuring, and similar tasks. The device may be used for square wave generation, gated delay signals, single pulse of controlled duration, and pulse width modulation as well as system interrupts. Here it is used to measure the pulse width.

The interface of the MC6840 chip to MC68000 bus is shown in Fig. 3.35 and Table 3.8 gives the register addressing concerned.

Table 3.8

Register selected address					Operation	
Address	A3 RS2	A2 RS1	A1 RS0	A0	R/W = 0	R/W = 1
\$30050	0	0	0	0	CR20=0 Write CR3 CR20=1 Write CR1	No operation
\$30052	0	0	1	0	Write CR2	Read SR
\$30054	0	1	0	0	Write MSB buffer register	Read counter 1
\$30056	0	1	1	0	Write timer 1 latches	Read LSB buffer counter
\$30058	1	0	0	0	Write MSB buffer register	Read counter 1
\$3005A	1	0	1	0	Write timer 2 latches	Read LSB buffer counter

Note: Because the MC6840 interfaces into the lower eight bits of the data bus, odd addresses must be used when the microprocessor accesses to the MC6840.

By properly programming the control register CR1 and CR2, timer 1 and timer 2 were defined into pulse width comparison mode. Table 3.9 explains the definition of the CR1 and CR2.

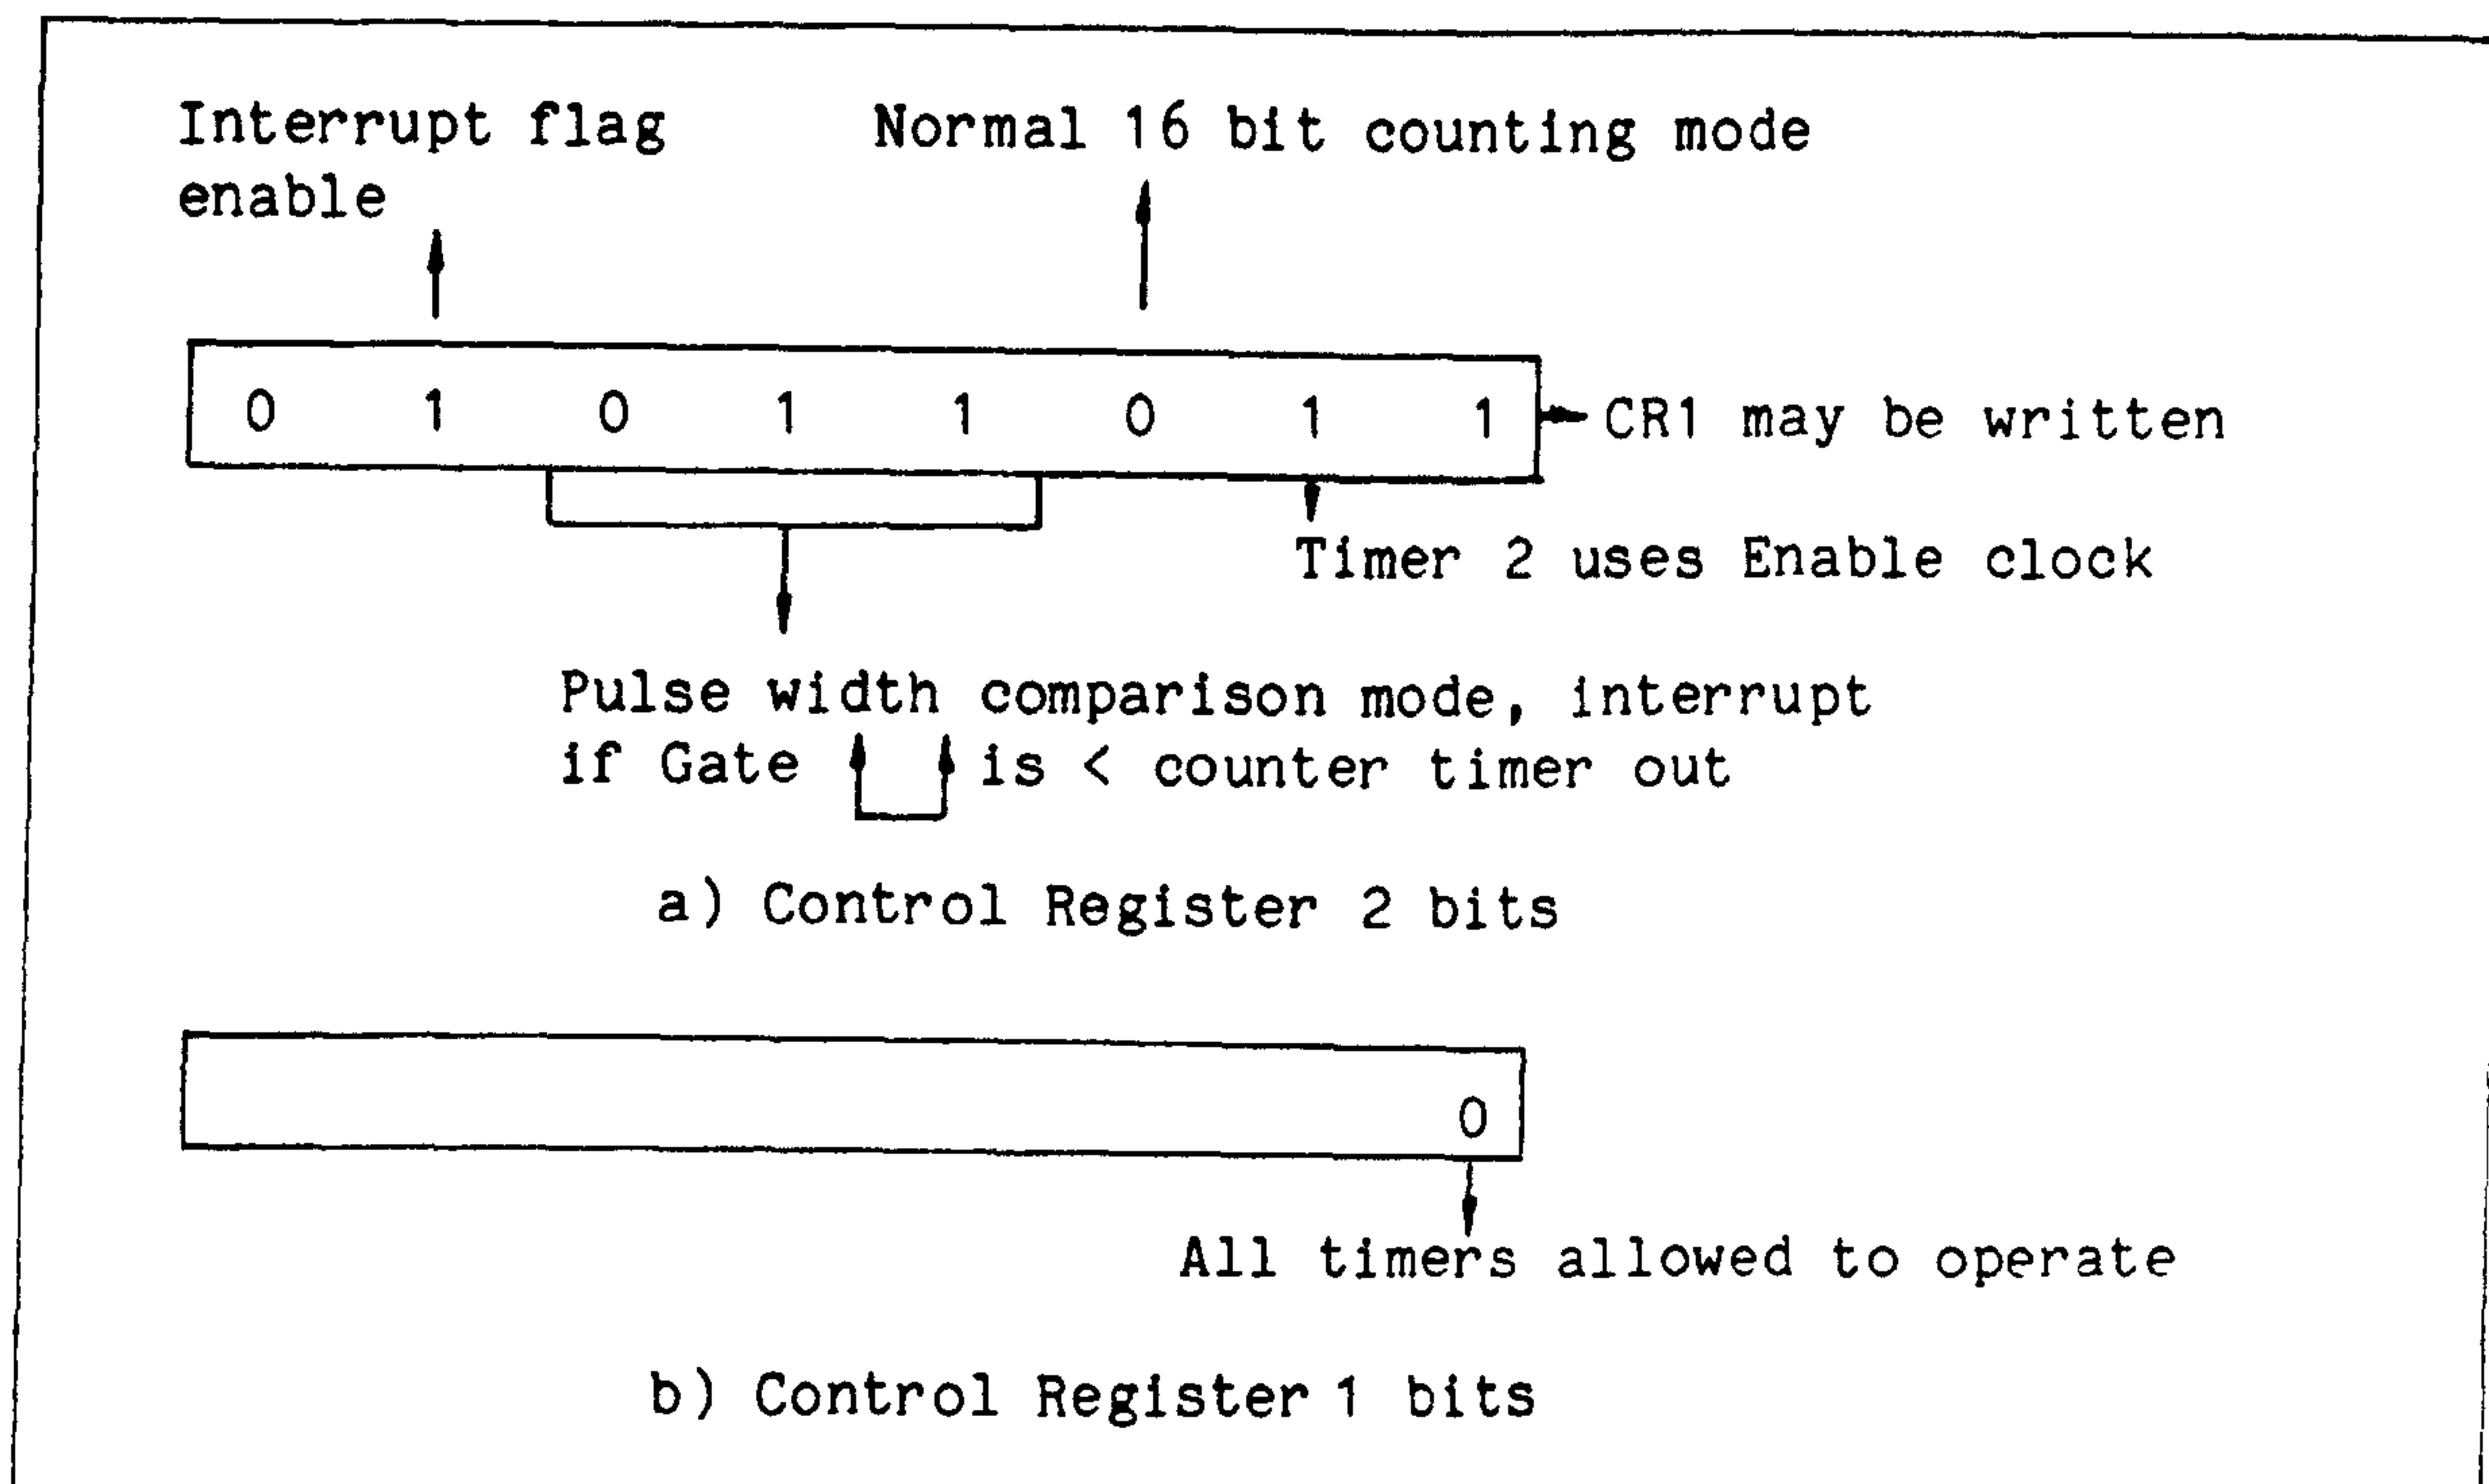

Table 3.9

In this case, timer 1 and timer 2 were programmed to measure the width of the pulses at the Gate inputs. After a write timer latch command was issued, a negative transition of the Gate input enabled the counter to decrement on each clock signal recognized (Enable clock 4×10^5 Hz), and positive transition of Gate input would terminate the count. Thus, the pulse width could be calculated from the reading of the counter and the frequency of the Enable clock. The following example will reveal the programming method for the MC6840.

```

INI:  MOVE.B #$5B,  $30053  ;
      MOVE.B #$5A,  $30051  ; set CR1 and CR2 into pulse
                                   ; width comparison mode

      MOVE.B #$FF,  $30055
      MOVE.B #$FF,  $30057  ; Counter 1 = $FFFF
      MOVE.B #$FF,  $30059  ;
      MOVE.B #$FF,  $3005B  ; Counter 2 = $FFFF

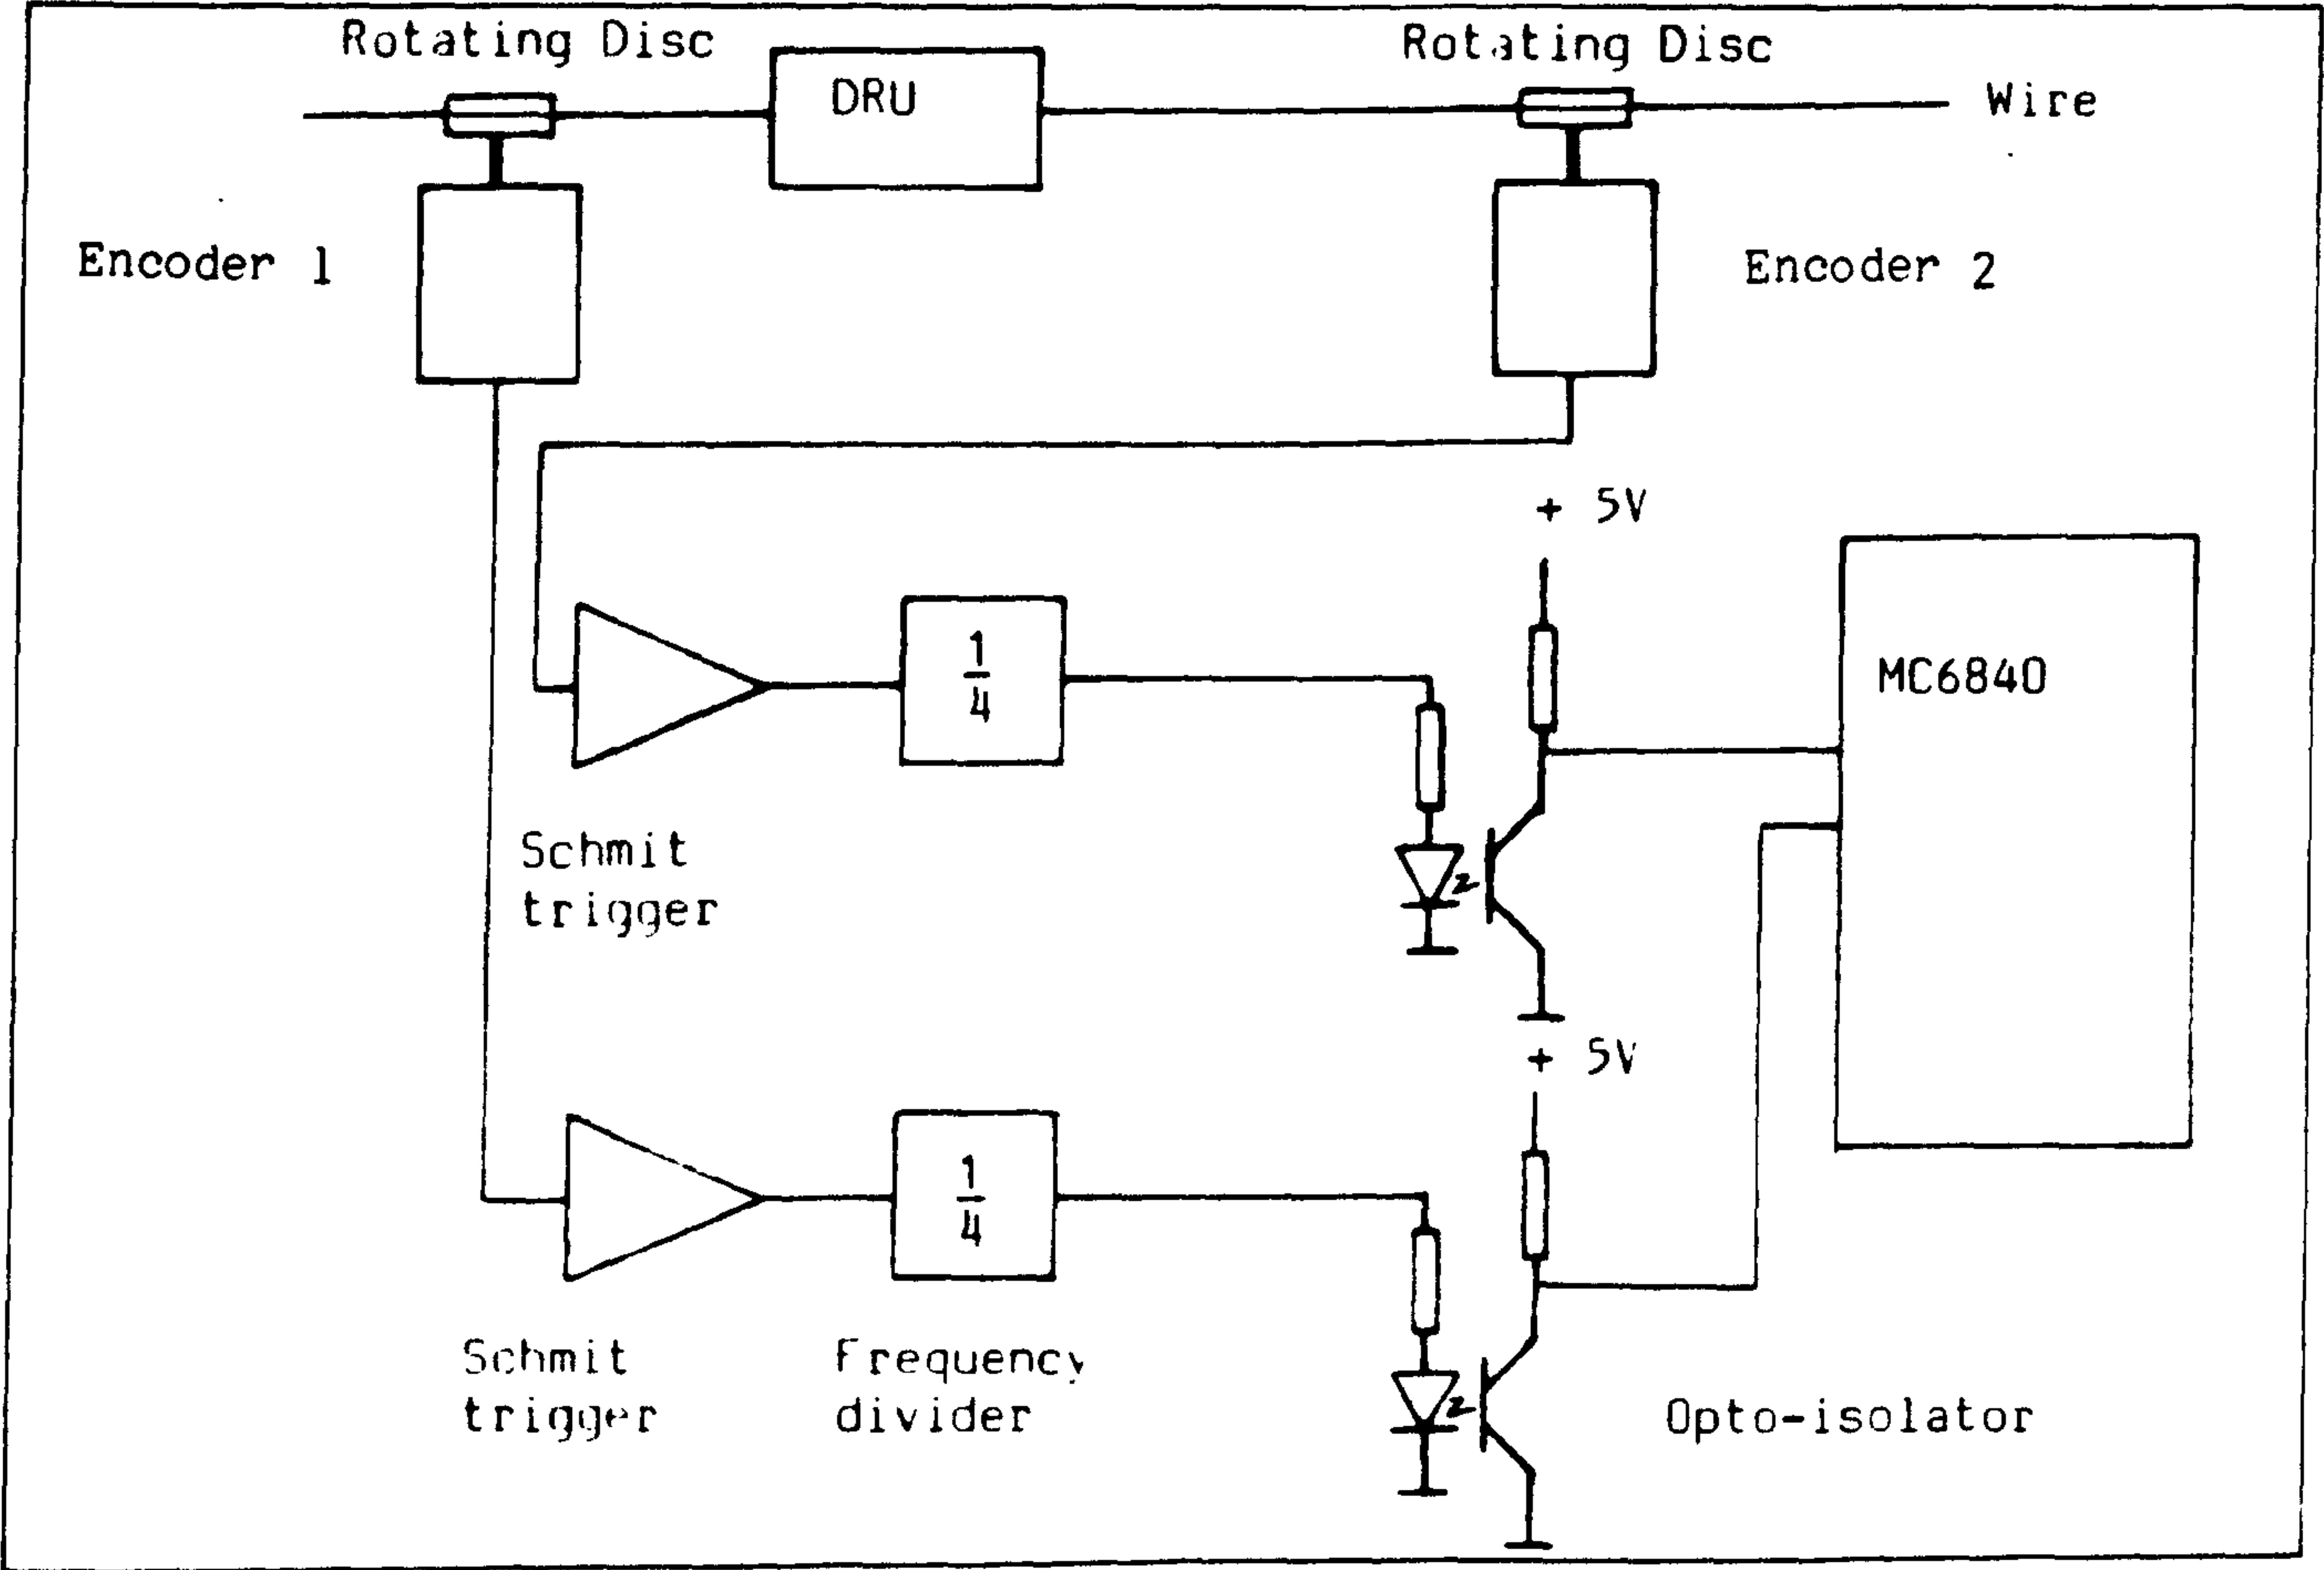

```

When negative transitions appeared at Gate 1 and Gate 2 inputs, counter 1 and counter 2 started to decrement on each Enable clock recognized, and positive transitions of Gate 1 and Gate 2 inputs would terminate the count, Fig. 3.34b shows the timing diagram. If the reading

from counter 1 and counter 2 are \$FBDF and \$FC42 respectively, the pulse width will be

$$T1 = \$420 / 400000 = 1056 / 400000 = 2.64 \text{ ms}$$

and $T2 = \$3BD / 400000 = 957 / 400000 = 2.39 \text{ ms}$

a

b

Fig. 3.34 a) The Scheme for the Reduction in Area Transducer
b) The Timing Diagram

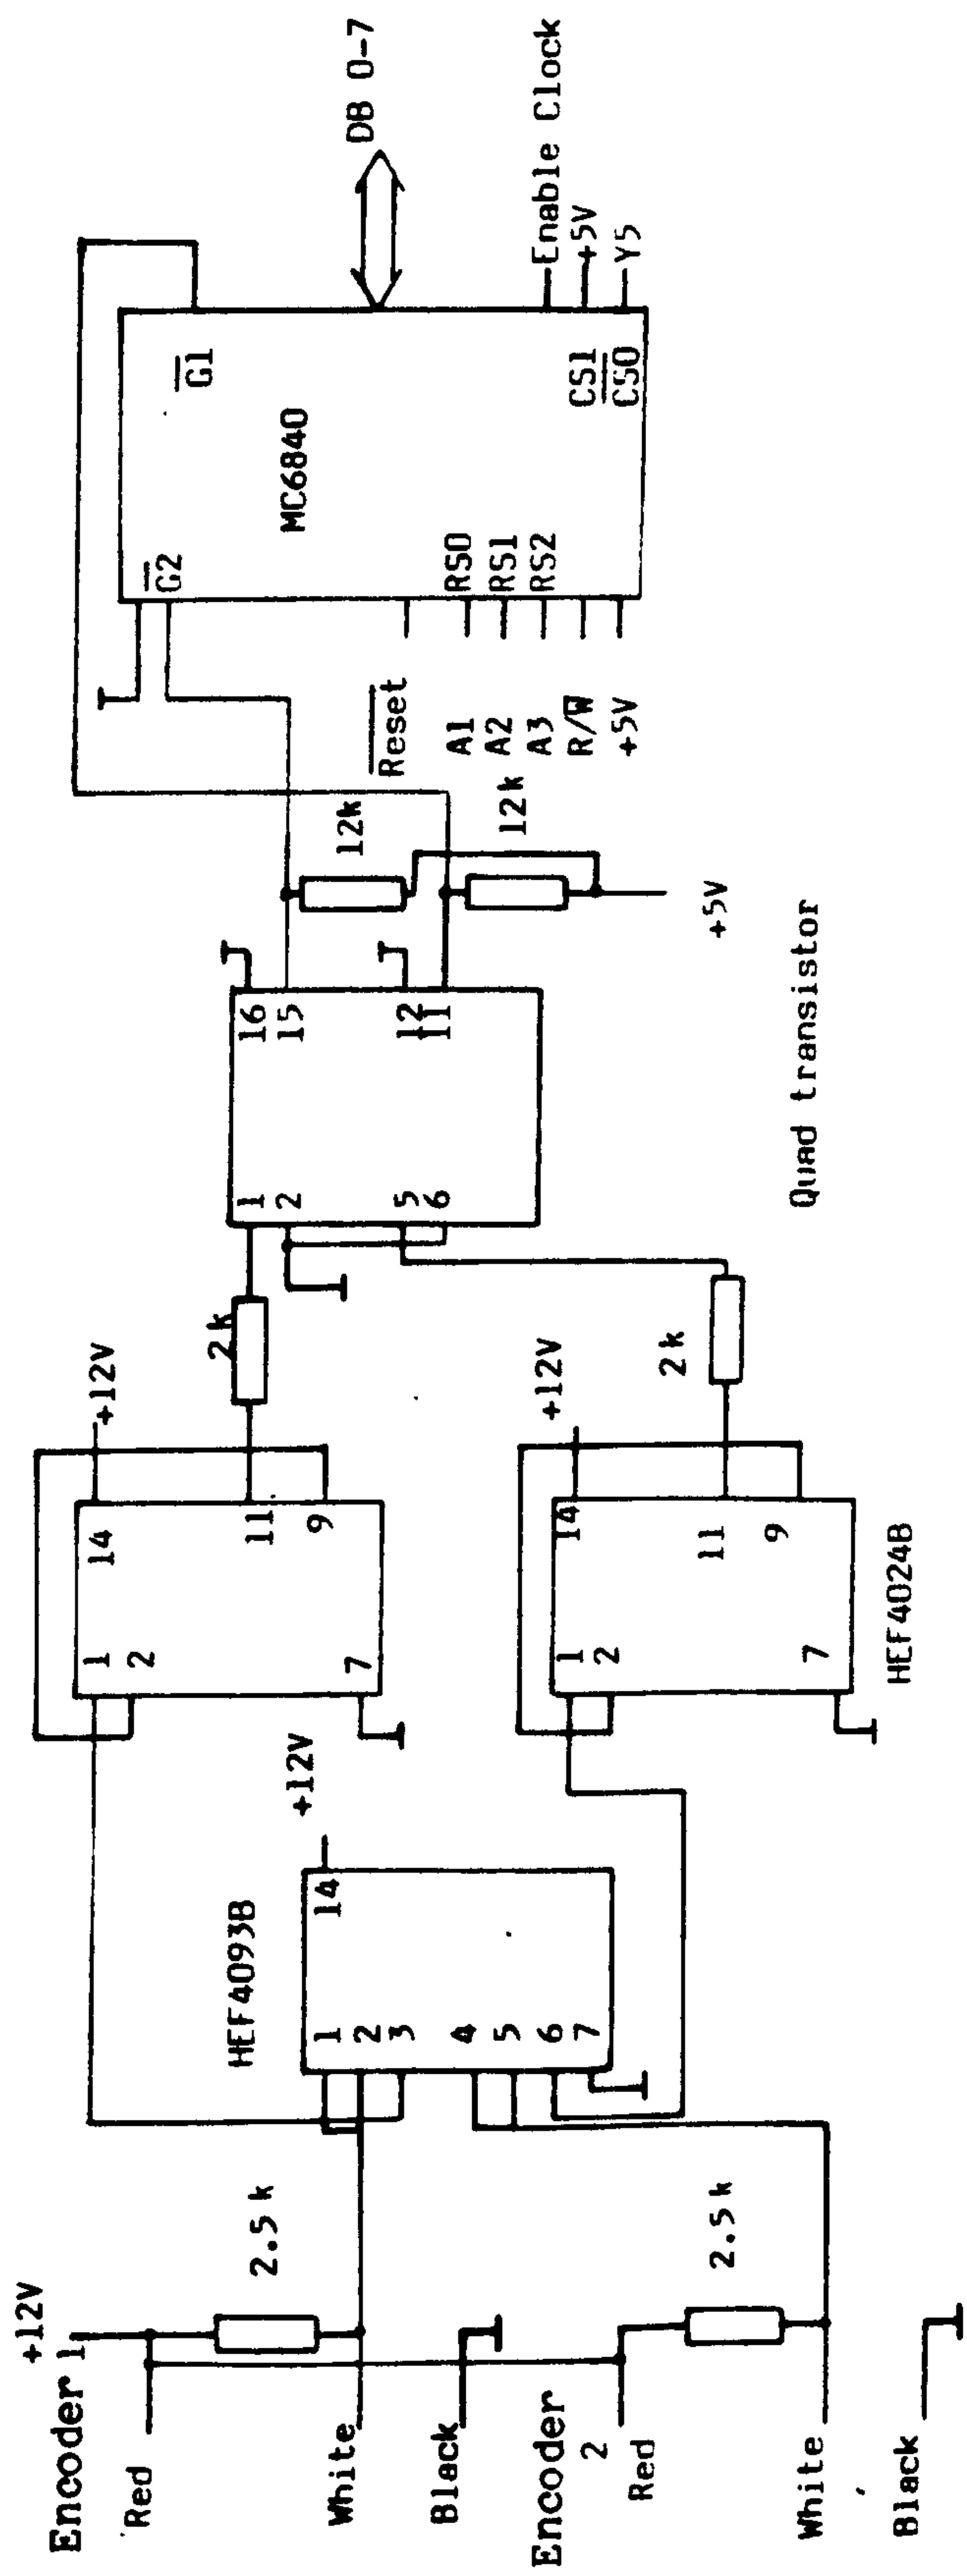

Fig. 3.35 The Diagram of the Interface Circuit

Plate 4

The T method [22] was used for pulse train processing, i.e., the detecting time was the width of the pulses received from the encoders. However, with this method the measuring accuracy decreases as the speed increases. At the highest drawing speed of 1.3 ms^{-1} , the frequency of the pulses reaches its maximum value

$$F_{\text{max}} = V_{\text{max}} * 100 / L = 1300 \text{ Hz}$$

Where L is the circumference of the rotating wheel and $L=100 \text{ mm}$. Noting that the frequency is divided by 4 and the width of the pulses is

measured, we have

$$CB = 2 F_c / F_{max} = 615$$

Where CB is the counting number during the duration of one pulse width, and F_c the frequency of the counting clock, $F_c = 400$ kHz. Then the maximum possible error in measurement is given by

$$\text{Error} = 1 / 615 = 0.16\%$$

Similarly at the lowest drawing speed of 0.1 ms^{-1} , the minimum frequency of the pulse is

$$F_{min} = V_{min} * 100 / L = 100 \text{ Hz}$$

Thus, the maximum detecting time is 20 ms.

3.7.2 - On Line Percentage Reduction in Area Indicator

In this case, the transducer interfaced with the MC68000 facilitated an on line indication of the percentage reduction in areas during the wire drawing process. The microcomputer calculated the actual PRA from the measurement of the transducer and showed the value of the PRA on the screen for every given period. A very simple program loop was used to work from sampling data to sending the PRA to the VDU. Fig. 3.36 shows the flowchart of the program and the listing of the program is given in Appendix 7.

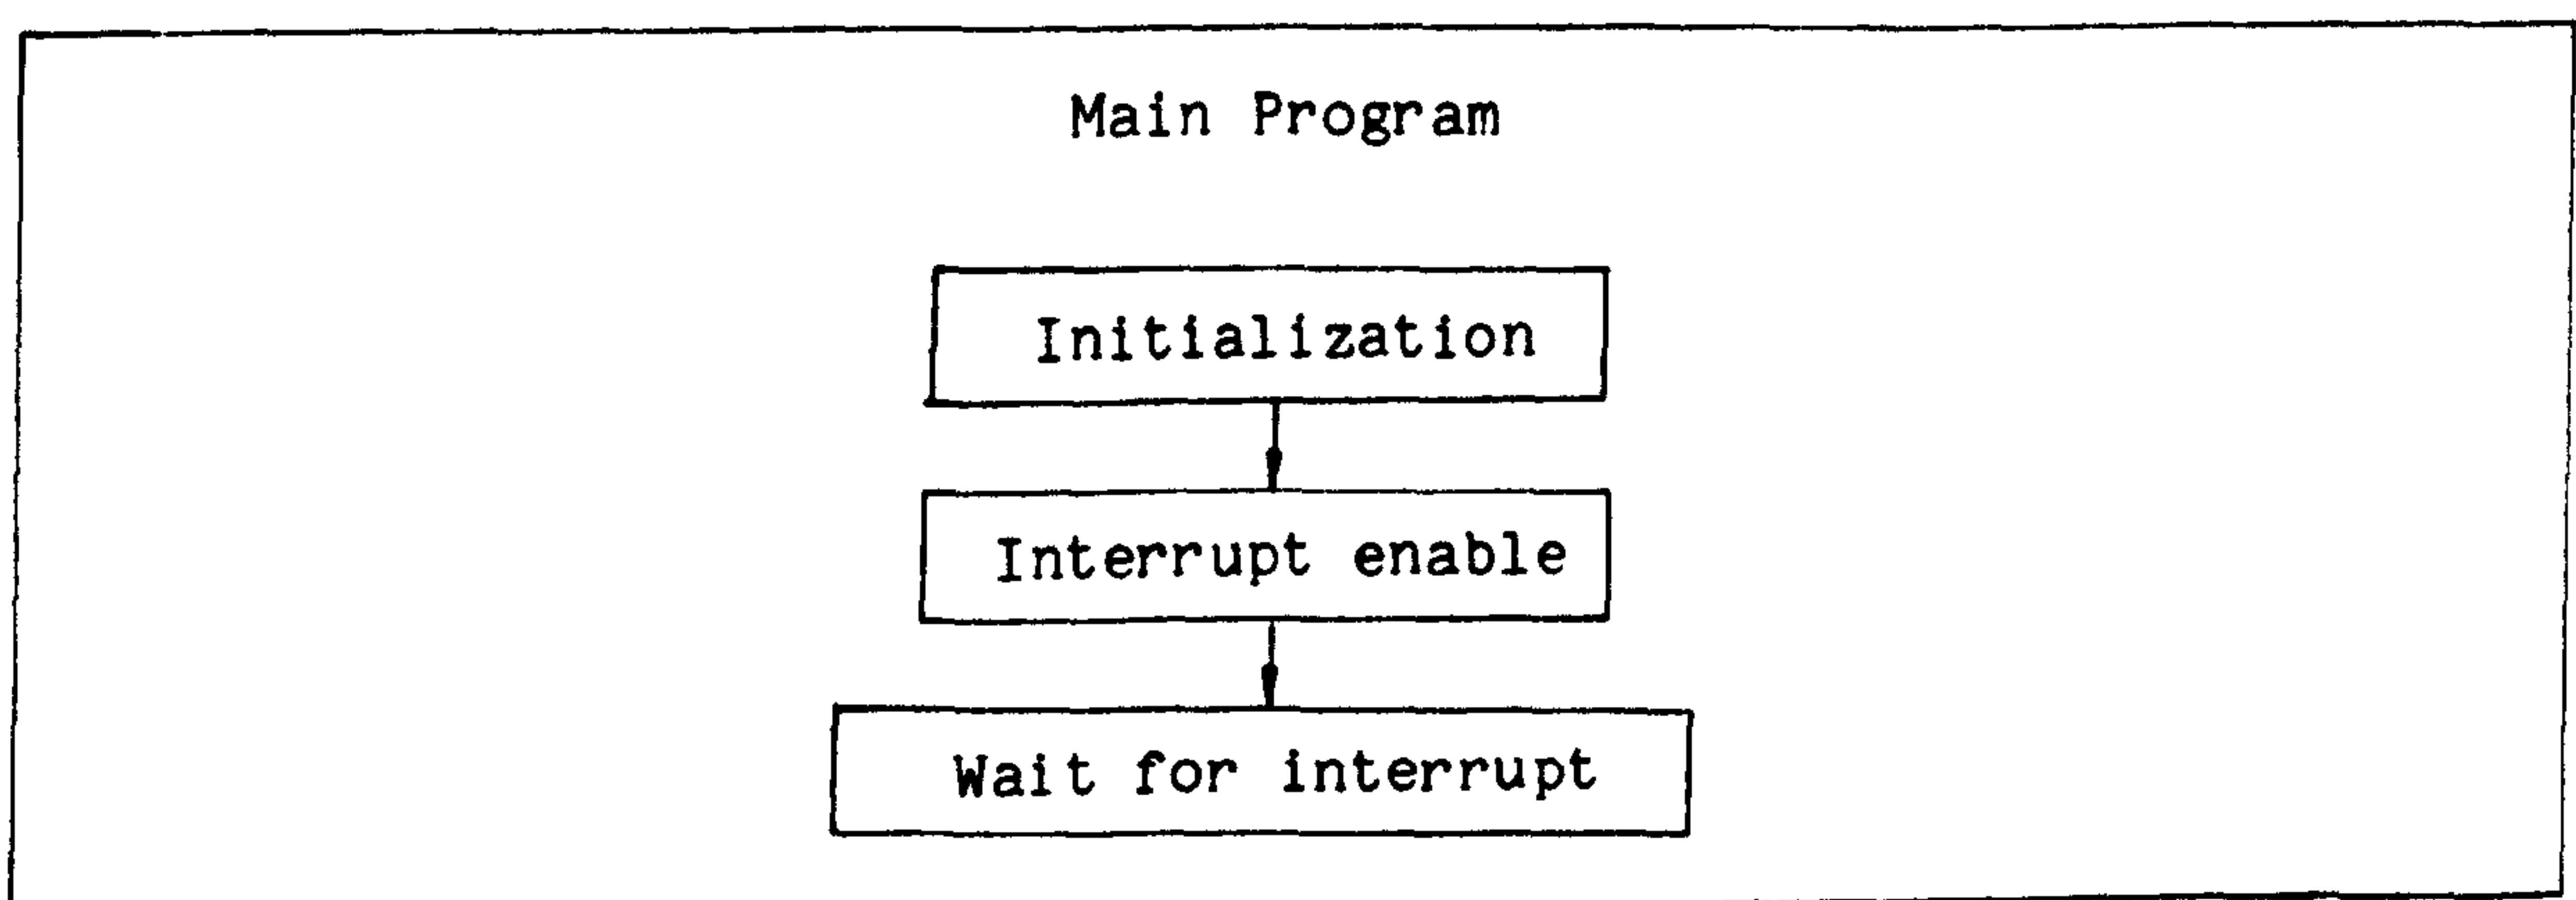

Fig. 3.36 Flowchart of the Program for the PRA Indicator

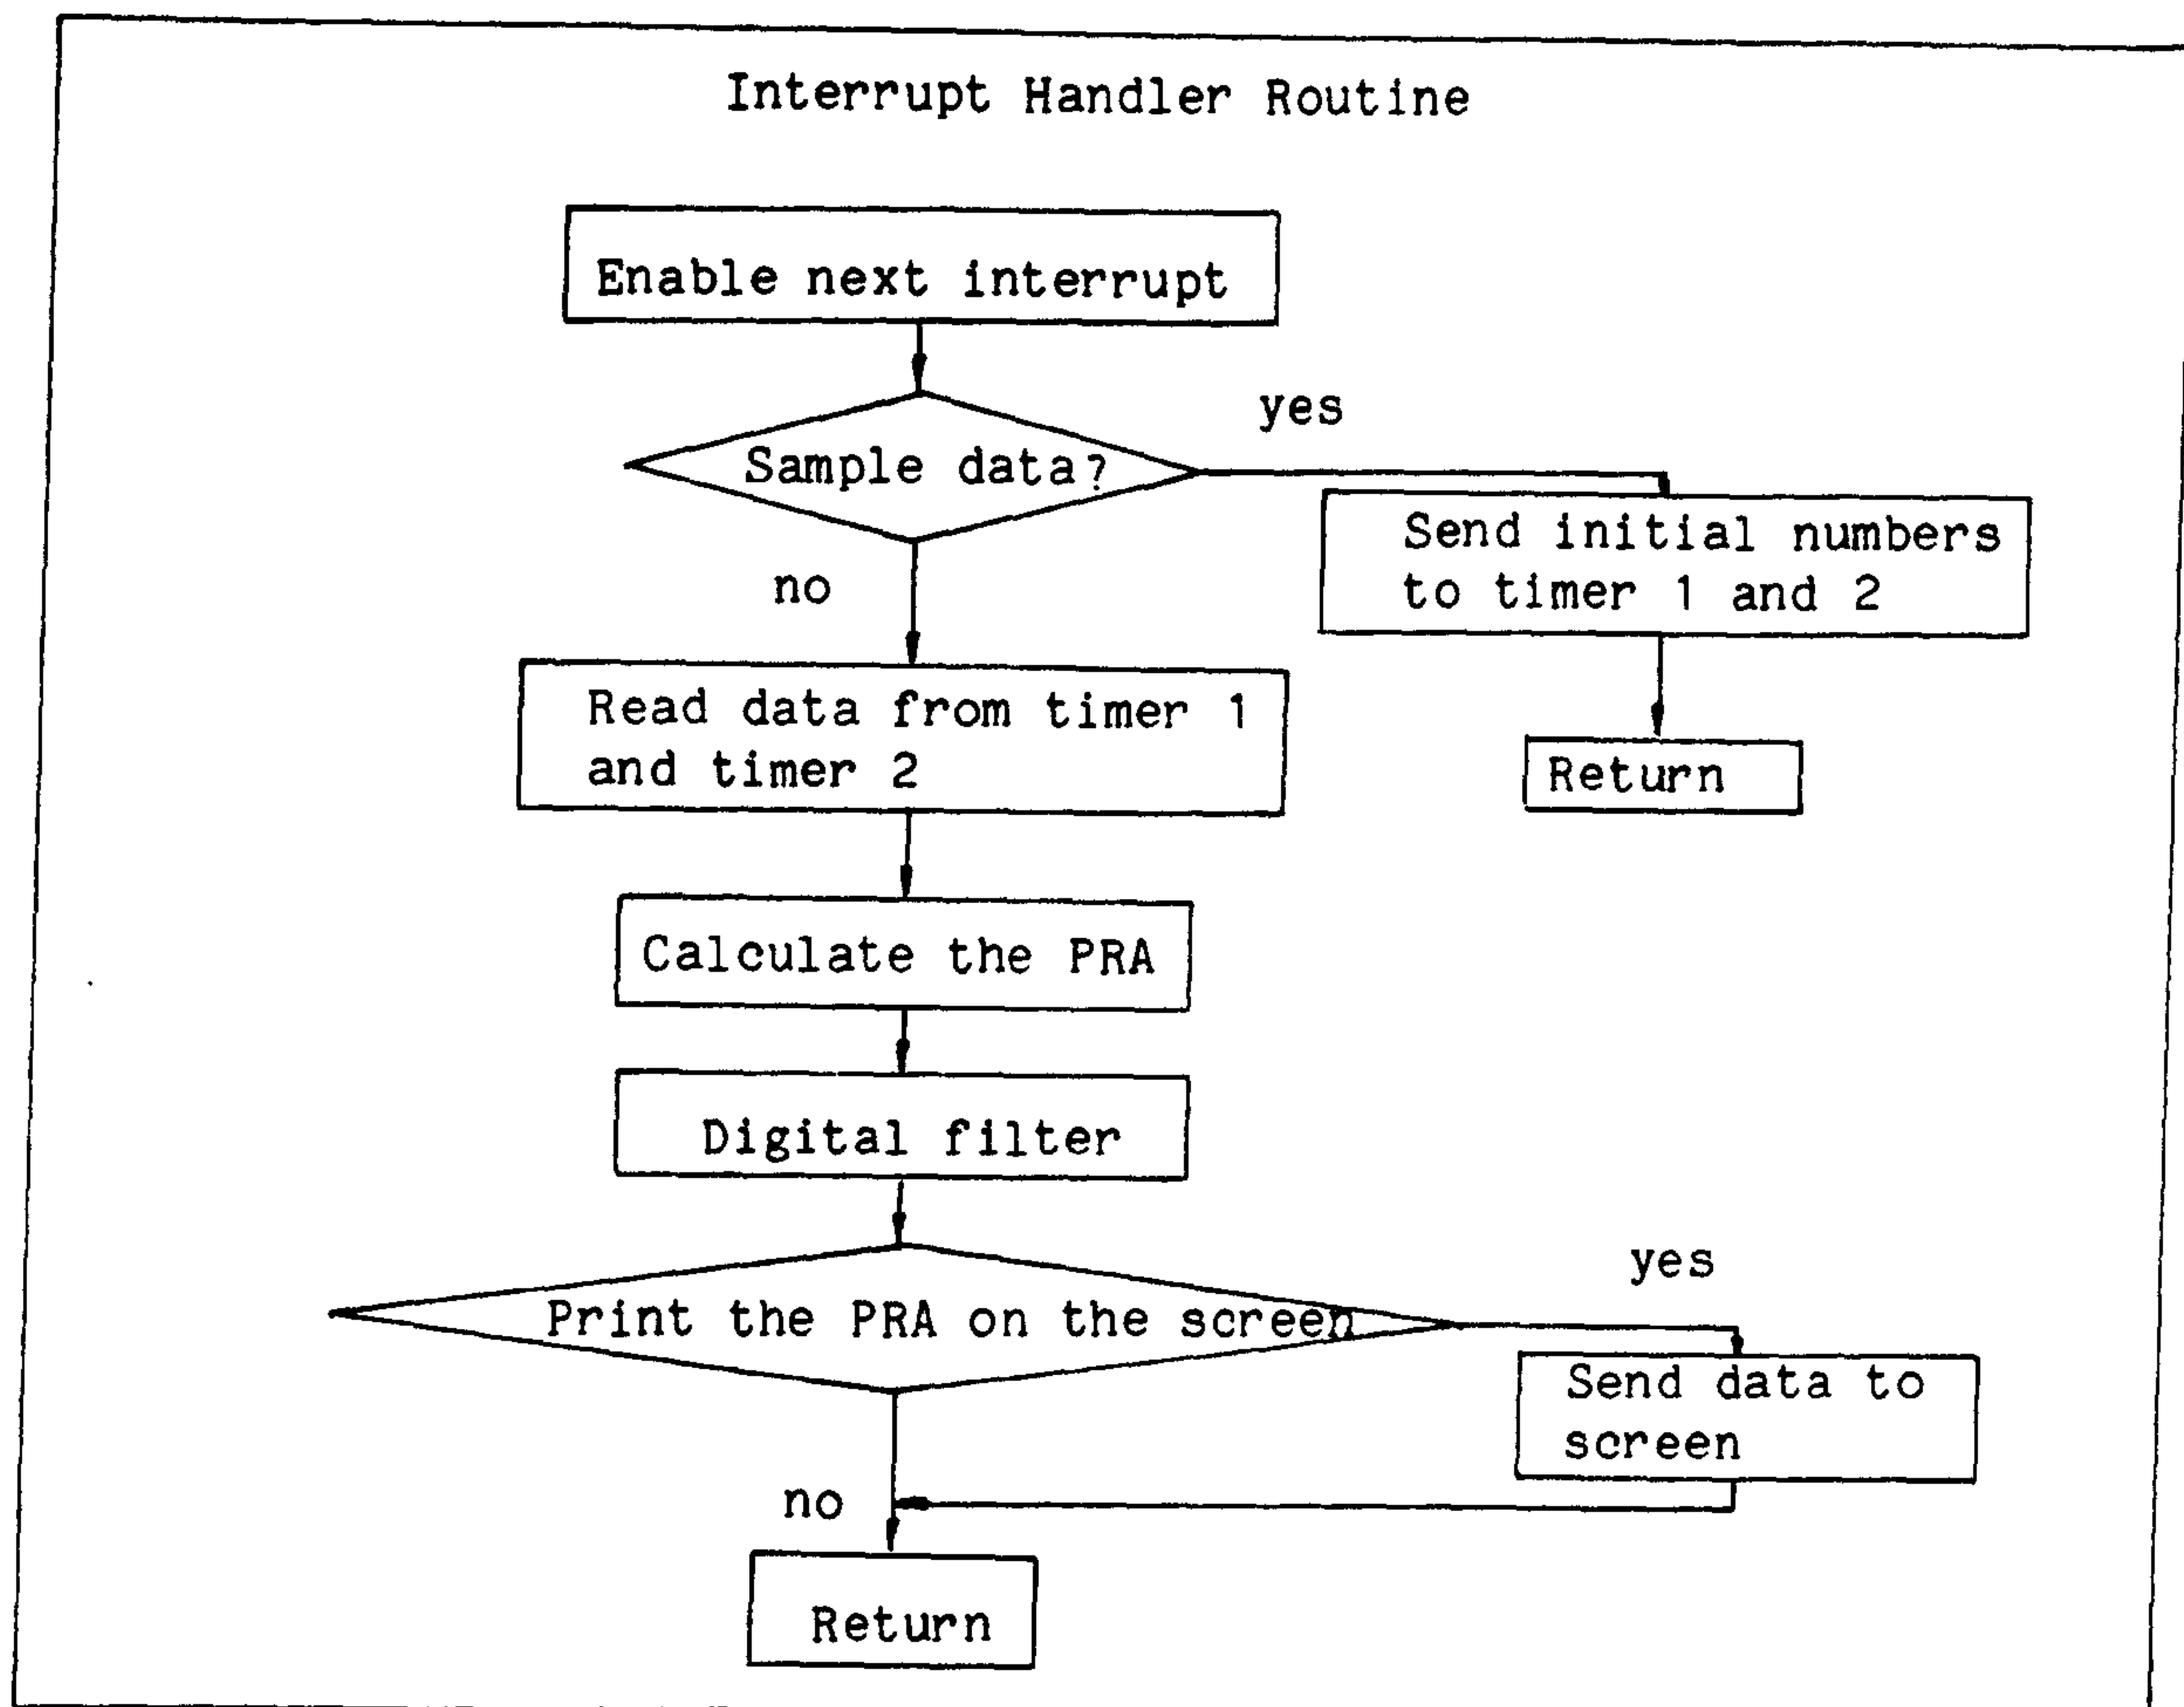

Fig. 3.36 Flowchart of the Program for the PRA Indicator

In determining the lowest drawing speed, a 40 ms sampling period was employed. An initial value of \$FFFF was sent to each timer and thus the timer was enabled to start counting. If the counting values of the timer 1 and timer 2 were N_1 and N_2 respectively, then

$$PRA = (1 - N_2 / N_1) * 100$$

The arithmetic average of the last 10 samples was used as the algorithm of a digital filter. To show the value of the PRA in decimal notation on the screen, two TRAP 14 handler routines provided by the MC68000 resident firmware package were used. One was HEX2DEC which converted 8 bit hex number found in register D0 to the equivalent decimal number, the other, OUTICR, output a string to the VDU. The number of the PRA in decimal was of 3 characters, tens, units, and tenths, with the decimal point implied.

3.7.3 - Closed-Loop Control System

In this configuration, the microcomputer calculated the PRA from the measurement of the transducer, compared the calculated value with the PRA setpoint to find the error, and determined the manipulated signal to control the drawing speed to bring the PRA to its setpoint value.

The theoretical analysis in chapter 2 only provided a steady state model of the dieless wire drawing process. Figs. 3.37a and b show some experimental results of the dynamic characteristics of the dieless wire drawing process, in which the drawing speed increases linearly and the PRA also follows to increase linearly. Compared with the time constants of the drive elements, the dieless wire drawing process has a relatively small time constant, and thus the dieless wire drawing process may be assumed to be a proportional element. The transducer also is a proportional element and the hydraulic drive system is a second order system. Thus, the block diagram of the control system is as shown in Fig. 3.38.

In Fig. 3.38, the gain K of the process including the hydraulic drive system, the dieless wire drawing process, the transducer, and the interface circuit was set to 1. A proportional controller with gain $K_p=1$ was simply employed to implement the closed-loop control system. The steady error could be eliminated by intentionally off-setting the value of the setpoint. In this case, the setpoint was $2 \times \text{PRA}$, where the PRA was the desired value. The algorithm for digital filtering was to calculate the arithmetic average of 5 last sampled data. Fig. 3.39 shows the flowchart of the program for drawing the wire of a uniform diameter and the program listing is given in Appendix 8.

3.8 - Results and Discussion

Test Procedure

The following procedure was followed to carry out a test. The power supplies for heater bands and other instrumentation were first switched on. The user program was loaded into the microcomputer from a tape and the program was executed from its starting address by an execution command. Following the prompt on the screen, the operator input the specification via the keyboard, and then the program execution was restarted. The temperature of the polymer melt in the polymer hopper and chamber were controlled by the microcomputer at the preset values. After 80 minutes for temperature to reach a uniform distribution state, wire from the coil was passed through the guides and over the pulley before being inserted and pulled through the PRA transducer and the DRU, then wound onto the bull block. The air pressure was put on, the hydraulic pump was started and the pressure valve was turned down to build hydraulic pressure up to 100 psi. Again the control program execution was restarted and the wire drawing process started.

Results

The hydraulic motor controlled by the microcomputer operated smoothly at its speed setpoint and the performance of the speed control system was shown by the speed step response in Fig. 3.30 (p. 103). The 0.4 percent quantization error could lead to a hunting problem at slow speed in which the system output varied between two discrete positions about the particular setpoint. This hunting problem was not of much practical importance since the motor usually operated at high speed for maximum PRA. Even in the tapered wire drawing process in which the drawing speed varied in a rather wide range and the hunting problem

occurred, the error caused by the hunting was still within the allowed range of ± 2 percent. Fig. 3.40 shows the speed / time response of the hydraulic motor during a tapered wire drawing process, in which the speed range is set from 0.02 ms^{-1} to 1.14 ms^{-1} and the total drawing time is about 5 seconds.

Fig. 3.40 Speed / Time Response During a Tapered Wire Drawing Process

The temperature of the polymer both in the polymer hopper and melt chamber was controlled thermostatically at its preset level to within $\pm 3^\circ\text{C}$ variations and the experimental results showed that with this accuracy, the requirement of producing products of the correct quality was met.

During the drawing process with a constant speed, the PRA indicator worked well over a wide measurement range from less than 1 percent to the maximum percentage reduction in area. In particular, at high drawing speed, the fluctuation of the reading of the indicator was very small. Plate 5 shows two pulse trains from encoders 1 and 2 respectively at a drawing speed of about 1 ms^{-1} , and a reduction in area of about 10

percent. The difference between the periods of the two pulse trains is clearly evident. However, when a rapid change occurred in drawing speed, the reading of the indicator fluctuated seriously and only after a relatively long period, did it become stable again. The most serious case of the measurement fluctuation is illustrated in Fig. 3.41. Here after a rapid change in the drawing speed as shown in Fig. 3.25 (p. 96), the readings of the indicator fluctuated over a wide range. In Fig. 3.41, all the readings above 11.6 percent are faulty and the actual measured values of the PRA during this process never showed larger values than 11.6 percent. The main problem causing this faulty reading stemmed from the mechanical driving parts. The encoder was driven by wire through a "friction" contact. During the process of a rapid change in drawing speed, because of the inertia of the encoder and the driving disc, slip between the wire and the disc might occur. During the process of a slow change in drawing speed, the indicator maintained the correct reading.

The fluctuation in readings during the process of a rapid change in drawing speed gave rise to difficulties in using this transducer to implement a closed loop control system. Some caution had to be exercised in order to reduce the oscillation during the transient part of the process. A digital filtering method was employed in sampled data processing. Even so, the final closed loop control system appeared not to work as well as expected, and its performance did not meet the requirement of drawing the tapered wire.

A qualitative test was conducted to examine the products using dieless wire drawing method controlled by microcomputer. The results of the test showed that the PRA kept close to the desired value with ± 2 percent allowed errors over long length. Also, the fluctuation of the measured diameter of the products was very little, and close to that

measured in the original wire diameter, so the products had good uniformity in diameter. Figs. 3.42 to 3.45 show some results of the tapered wires produced, from the variations of the PRA versus the length of the produced wires, the uniformity of the change in the area of the tapered wires is demonstrated.

Fig. 3.43 PRA / Length of the Produced Tapered Wire

Fig. 3.44 PRA / Length of the Produced Tapered Wire

Fig. 3.45 PRA / Length of the Produced Tapered Wire

Discussion

The design of the speed and the temperature control systems was primarily based on the requirement of ± 2 percent allowed error in the area of the produced wire. The tachogenerator introduced the main error to the control system and the 8-bit DAC and ADC with 0.4 percent resolution also added some error into the system. For high quality of products, the performance of the system can be easily improved by using digital speed measurement approach or 10 bit ADC and DAC. However, the complexity of the system will be increased and only for specially high quality of products would this improvement need to be considered.

Tapered wires with different size could be easily produced by this dieless wire drawing method. To date no other method using conventional wire drawing for the production of tapered wires has been reported.

The PRA indicator worked well under steady-state conditions, but fluctuation in readings occurred under transient conditions. To enable a closed-loop control system with good performance to be built using the PRA as a feedback signal, the mechanical components of the transducer require some redesign.

Notation

K_P	Proportional gain
T_I	Integral time constant
T_D	Derivative time constant
g_i	Coefficient of z^{-1} in $G(z^{-1})$
T	Sampling period
h_i	Coefficient of z^{-1} in $H(z^{-1})$
a_i	Coefficient of z^{-1} in $A(z^{-1})$
b_i	Coefficient of z^{-1} in $B(z^{-1})$
c_i	Coefficient of z^{-1} in $C(z^{-1})$
t_i	Coefficient of z^{-1} in $T(z^{-1})$
p_i	Coefficient of z^{-1} in $P(z^{-1})$
f_i	Coefficient of z^{-1} in $F(z^{-1})$
$u(t)$	The control increment
$U(t)$	Sequence of controller output variables
$e(t)$	Error
$A(z^{-1}), B(z^{-1}), C(z^{-1})$	System polynomial in z^{-1}
$Y(t)$	Sequence of system output variables
$\zeta(t)$	White noise sequence
$\phi(t)$	Pseudo system output
$P(z^{-1}), Q(z^{-1}), G(z^{-1}), P_n(z^{-1}), P_d(z^{-1}), H(z^{-1}), F(z^{-1})$	polynomials in z^{-1}
$W(t)$	Reference value of system output
$\phi_y(t)$	Filtered system output
$T(z^{-1})$	Desired closed loop characteristic polynomial
$\varepsilon(t)$	Estimation error
$Z(t)$	Vector of delayed input / output variable
$\theta(t)$	Vector of controller polynomial coefficients

$P(t)$	Covariance matrix
$\overline{P(t)}$	Finite memory version of $P(t)$
ρ	Forgetting factor
I	Unit matrix
ω_n	Natural frequency of second order system
ζ	Damping factor of second order system
K	System time delay (integer)
V	Control weighting
ρ_0	Coefficients down the diagonal of the initial matrix $P(0)$
T	Sampling period

4.1 - Digital PID Controllers

One of the most widely used controllers in the design of continuous-data control systems is the PID controller, where PID stands for proportional + integral + derivative control. Fig. 4.1 shows the block diagram of a typical continuous-data PID controller acting on an error signal $e(t)$. The transfer function of the controller is given by equation (4.1)

$$U(s) = (K_p + \frac{K_I}{s} + K_D s) E(s) \quad (4.1)$$

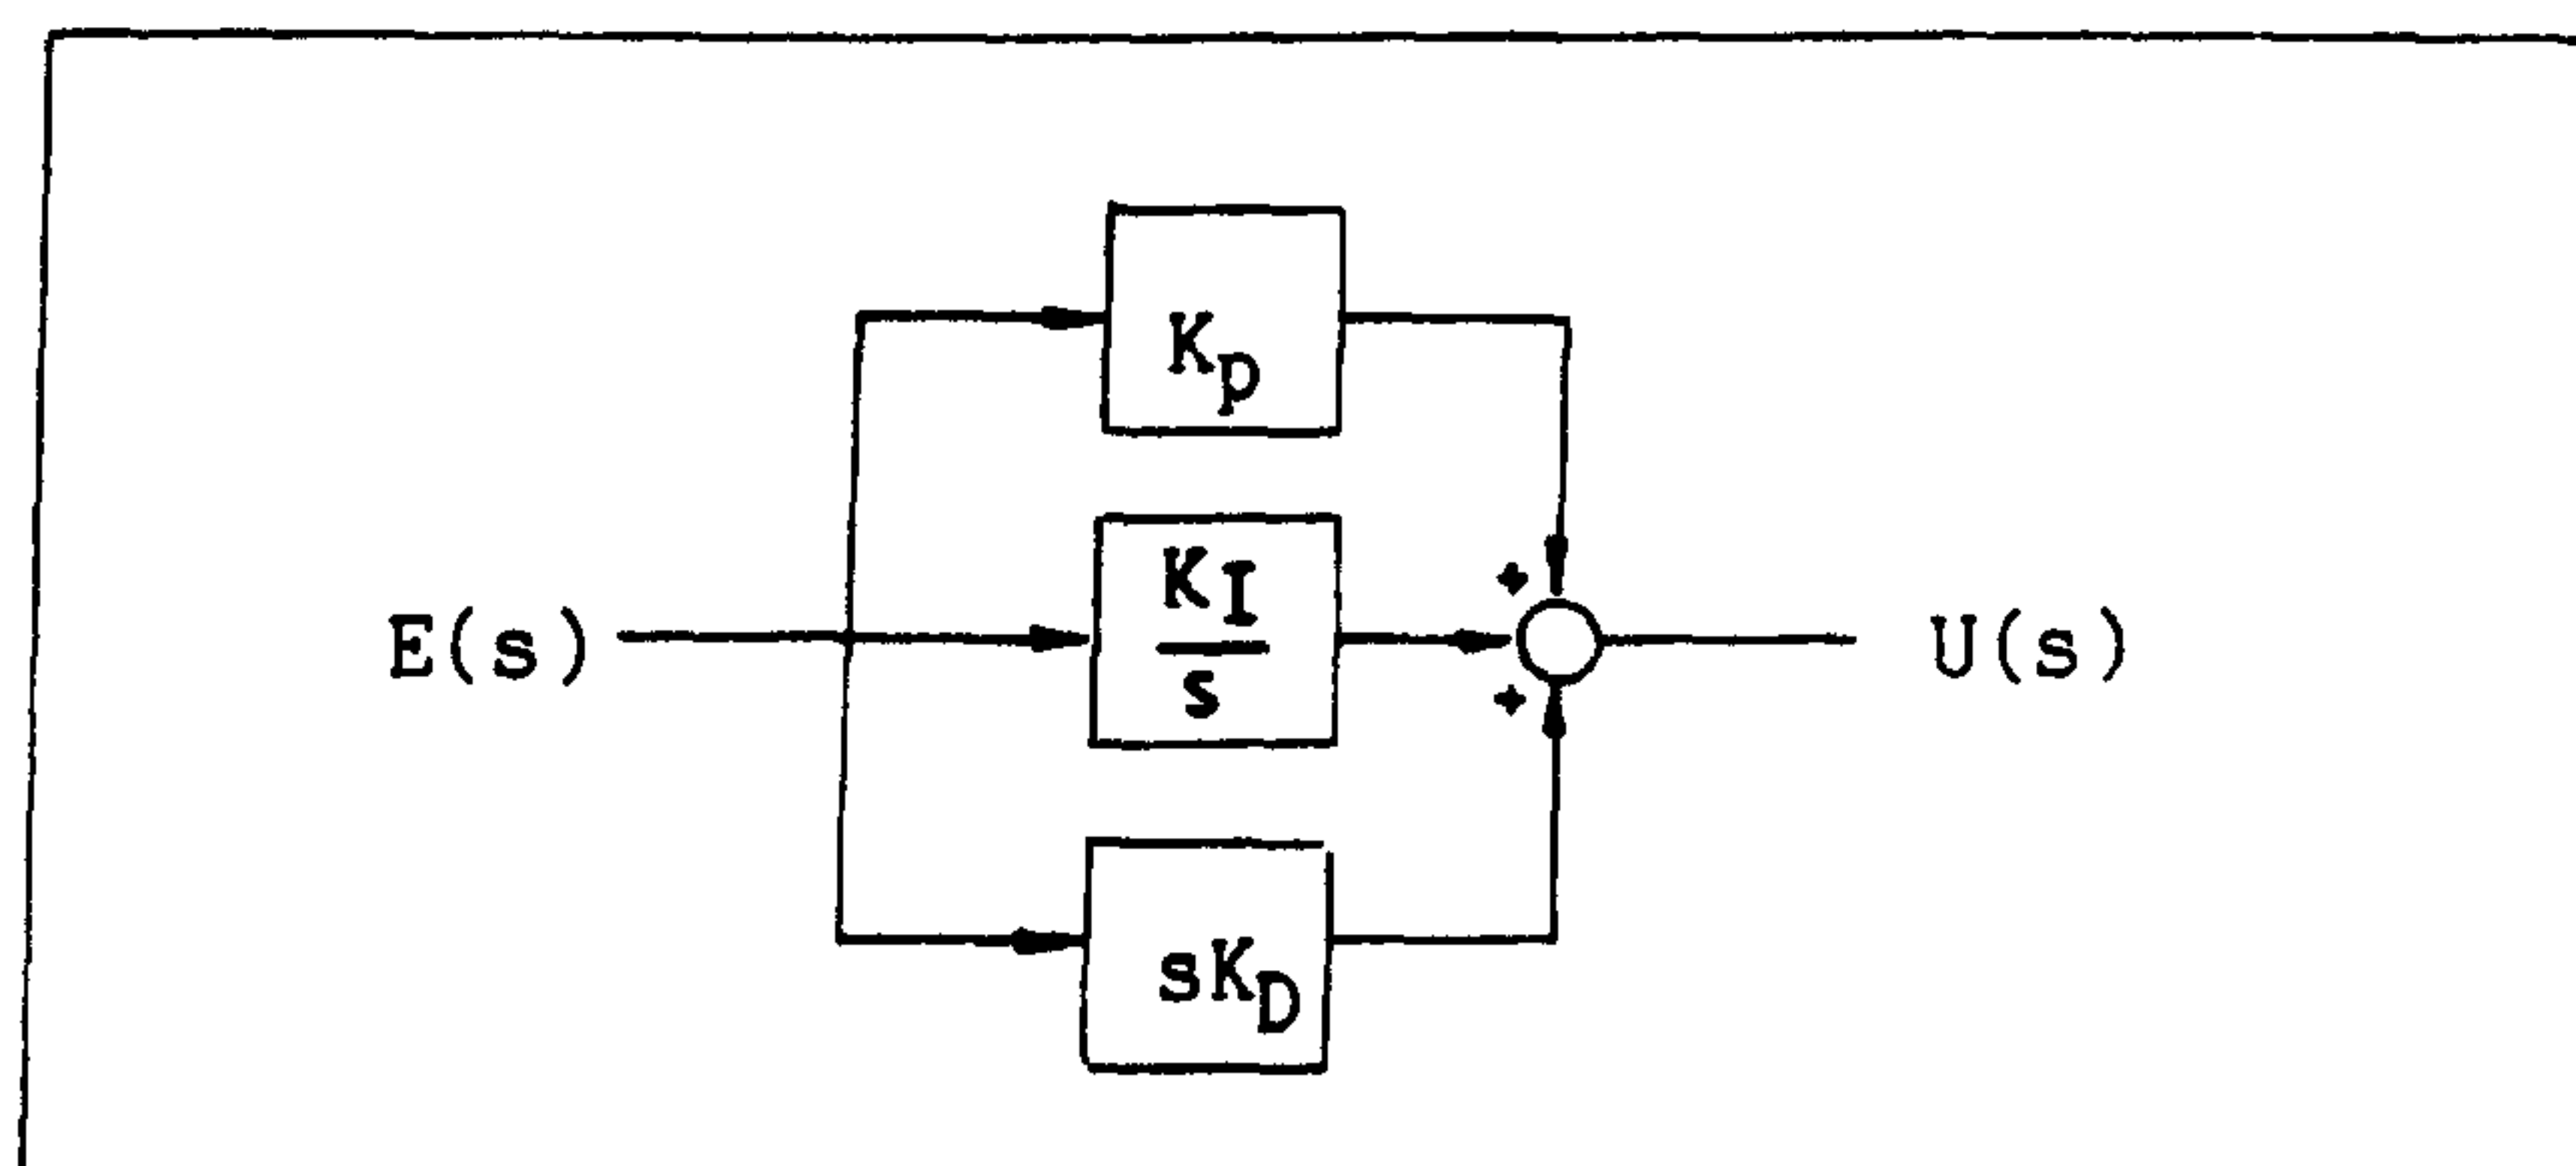

Fig. 4.1 A Continuous-Data PID Controller

There are several PID controllers with different structures up to the point where the only remaining common feature is the integral action over the error. We will consider here the basic structure[23], given by equation (4.2)

$$U(s) = K_p \left(1 + \frac{1}{T_I s} + \frac{T_D s}{1 + \frac{T_D s}{N}} \right) E(s) \quad (4.2)$$

where K_p , T_I , T_D are proportional gain, integral time, and derivative time respectively, N is a constant $\gg 1$.

The same principle of the PID control can be applied to digital control and there is a number of ways to implement a PID digital

controller. For example, taking Z-transforms on both sides of equation (4.2), we have the discrete-data transfer function of the PID digital controller, i.e.

$$U(z) = \frac{g_0 + g_1 z^{-1} + g_2 z^{-2}}{(1 - z^{-1})(1 + h_1 z^{-1})} E(z) \quad (4.3)$$

where

$$g_0 = (N + 1)K_p$$

$$g_1 = -K_p \left(1 + e^{-\frac{TN}{T_D}} + 2N - \frac{T}{T_I} \right)$$

$$g_2 = K_p \left(N + e^{-\frac{TN}{T_D}} - \frac{T}{T_I} e^{-\frac{TN}{T_D}} \right)$$

$$h_1 = - e^{-\frac{TN}{T_D}}$$

and T is the sampling period

After performing cross multiplication, the velocity form of PID controller is given by

$$u(z)(1 + h_1 z^{-1}) = (g_0 + g_1 z^{-1} + g_2 z^{-2}) E(z) \quad (4.4)$$

or

$$u(z) = \frac{G(z^{-1})}{H(z^{-1})} E(z)$$

where

$$u(z) = (1 - z^{-1})U(z)$$

$$G(z^{-1}) = g_0 + g_1 z^{-1} + g_2 z^{-2}$$

and

$$H(z^{-1}) = 1 + h_1 z^{-1}$$

The PID controller can be easily implemented by a program in a digital computer and a number of alternatives to the PID controller described by equation (4.4) are available, [24] [25].

4.2 - Self-Tuning Controllers

In recent years, a great deal of attention has been focussed on adaptive control. Self-tuning controllers represent an important class of adaptive controllers; they are easy to implement and applicable to processes with a wide variety of characteristics: unknown parameters,

the presence of time delay, time-varying process dynamics and stochastic disturbances. The aim of the self-tuning algorithm is to carry out the synthesis, implementation and validation of a digital controller in an on-line manner. In its essential form, a self-tuning controller combines the sequence of identification, controller synthesis and implementation as shown in Fig. 4.2. The sequence is carried out at each sampling interval and proceeds in an iterative manner until the controller coefficients achieve steady values, at which point the identification and synthesis stages are stopped.

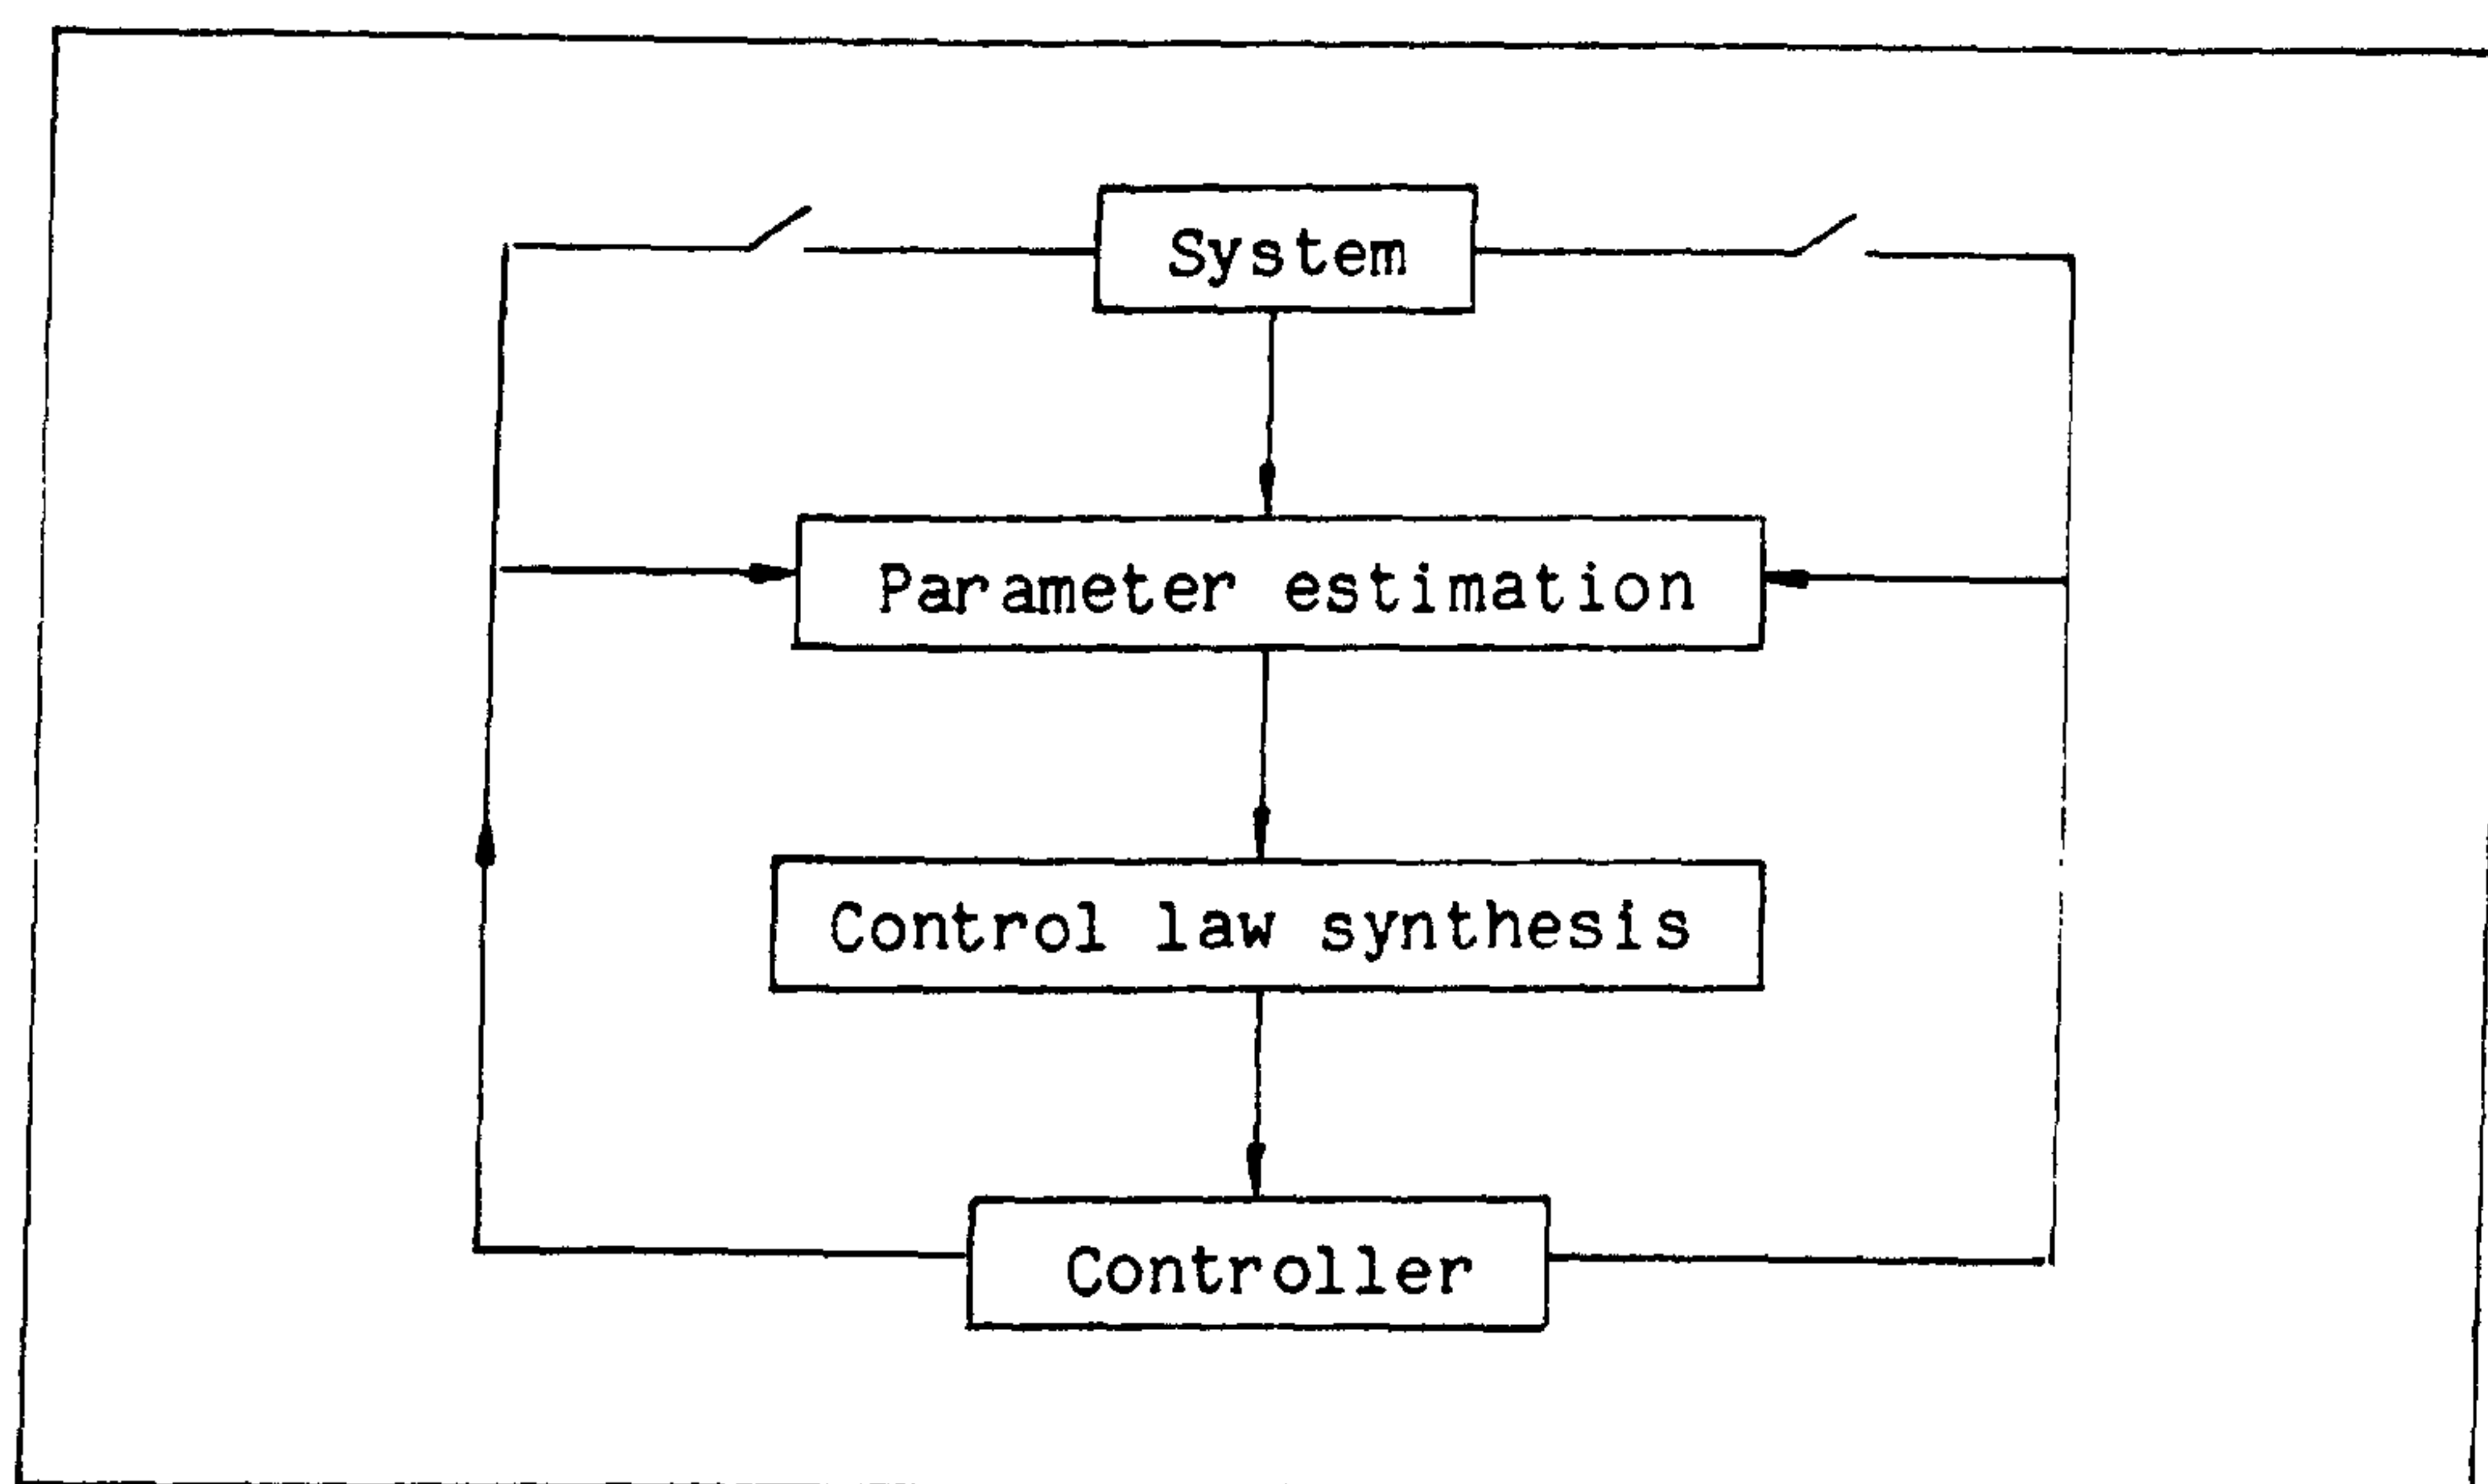

Fig. 4.2 The Self-Tuning Sequence

The first major development within this class of controllers was the self-tuning regulator (STR) designed to maintain a constant setpoint in the face of unmeasured disturbances [26] [27]. The technique is very sensitive to the presence of non-minimum phase characteristics. Also the control signals generated may be excessively large, such that the system actuators will saturate. A later development in the form of a self-tuning controller (STC), utilizes a more general control objective than the STR, by minimizing the variance of a generalized output (i.e. a combination of the output, input and setpoint). This approach allows

the STC to be applied to a wider variety of processes; for example, it can easily handle non-minimum phase systems, and setpoint tracking is incorporated directly in the algorithm. However, the technique requires a known time delay, so it is not applicable to a system which has an unknown time delay or one in which the time delay varies, unless such variation can be specified analytically, [28] [29].

The approach taken by Wellstead [30] [31], was to modify the STR, using pole assignment as the design criterion. The method is not sensitive to the presence of non-minimum phase characteristics; it can be detuned to avoid the excessive control action characteristic of minimum-variance controllers, and unknown or varying time delays can easily be handled. However, the number of polynomials which need to be chosen is more than for the minimum variance algorithm.

The weighted minimum-variance self-tuning controller [32] is based upon a k-step-ahead control law and can be used for unstable and non-minimum-phase plants. The controller includes control weighting and this results in relatively smooth control signals. The controller is also stable for ranges of control weighting where the STC is unstable.

The generalized STC with pole assignment [33] combines the suboptimal approach of the STC and the classical approach of pole assignment to yield robustness and ease of setpoint tracking.

All these schemes were developed for stochastic systems. The pole/zero assignment technique was also used to design a self-tuner for a class of deterministic systems [34]. Recently, it has been shown that the basic STC and the generalized STC with pole assignment can be used correctly for both deterministic and stochastic systems [35]. The algorithm of the generalized STC with pole assignment for deterministic systems avoids the polynomial factorization or a non-linear identification procedure as in [34], merely requiring the solution of a

polynomial identity.

Because of the desirable practical features of self-tuning control, its application to engineering almost came together with its theory. Cegrell and Hedquist, Borisson and Wittenmark have applied it to a problem within the paper industry as a regulator. The work was reported to be successful [36] [37]. The application by Borisson and Syding concerned the self-tuning control of an ore-crusher [38]. The target was to regulate the power absorbed by the crusher via control of ore feed-rate. Other such chemical process steady-state regulation problems [39], domestic heating system control [40] et al were also reported. The practical results have demonstrated the effectiveness of the self-tuners.

4.3 - Self-Tuning PID Controllers

It is clear that a self-tuning controller, in general, need not necessarily have a PID structure, and with the availability of cheap and fast computing capabilities, there is no justification to limit designs to simple PID controllers. Furthermore, powerful identification techniques are readily available to provide more accurate high order models than the second order approximation. Several papers have discussed these points [23] [41] [42]. The conclusions reached are in summary as follows:

(1) In the process industries, conventional PID control still predominates because it is robust and remarkably effective for a wide range of processes. It is also well-understood by many plant engineers.

(2) When faced with linear time-invariant plants, the PID controller design technique allows one to simply conduct the tracking capability-noise rejection compromise, given that low frequency

modelling uncertainty is overcome by the integrator's high gain. This allows the system to follow a step command with no steady-state error, even in the presence of a disturbance of unknown magnitude, as long as the closed-loop system remains stable. In a practical servo mechanism problem where the operating point moves as the output tries to follow the reference trajectory, the validity of the linearization of the process nonlinear differential equation is reduced. The integral term effectively cancels the most offending part of such an approximation error, the bias term.

(3) It is often difficult to establish a priority of economic benefits for proposed applications of modern control. Furthermore, the control system hardware cost is usually only a small portion of the total project cost.

However, the designer is faced with the requirement to detune the regulator parameters, thus reducing the performance, in order to cope with variations of gain and time constants at different operating points. In some industrial processes, fixed parameter controllers become inadequate because of more stringent performance requirements or the existence of large modelling uncertainties, or time varying plant.

Some controllers need regular retuning to account for process changes and ageing. Also there are some disadvantages associated with conventional PID parameter tuning techniques [42]. In PID process control, two tuning methods are commonly used: The first is the Ziegler-Nichols method and the second is the method by Chien. The former needs the ultimate gain and the period of ultimate oscillation at the stability limit. However it is often difficult to determine their exact values experimentally in real processes because oscillatory operation may have to be avoided. The latter method requires an exact form of the

process expressed by a transfer function. However many real processes fail to reveal their transfer functions.

Providing the PID controller with the capability of self-tuning (that is, adjusting its parameters from on-line measurements and the deviation from the desired index of performance - the tracking error) may be the possible solution to overcome these disadvantages . It is for the above reasons that the self-tuning PID controller described in this work was developed.

A self-tuning PID controller can be used in two different ways [24] [43]:

(1) To provide a procedure to automatically generate PID tuning constants instead of the usual trial-and-error procedure; after the PID settings have converged, the self-tuner can be turned off.

(2) To provide an adaptive control system in which the PID controller parameters are modified to adapt to a changing situation.

Several reported self-tuning PID controllers are summarized in the following sections.

4.3.1 - Self-Tuning PID Controllers Based on STC [24]

This is a modified version of the STC with PID structure. The process model is given by

$$A(Z^{-1})Y(t) = Z^{-K}B(Z^{-1})U(t) + C(Z^{-1})\zeta(t) \quad (4.5)$$

where $Y(t)$ is the measured output

$U(t)$ the manipulated input

$\zeta(t)$ an uncorrelated sequence of random variables

and t denotes the sampling instant, $t = 0,1,2,..$. The polynomials $A(Z^{-1})$, $B(Z^{-1})$ and $C(Z^{-1})$ are expressed in terms of the backward shift operator Z^{-1}

$$A(Z^{-1}) = 1 + a_1 Z^{-1} + \dots + a_n Z^{-n}$$

$$B(Z^{-1}) = b_0 + b_1 Z^{-1} + \dots + b_m Z^{-m} \quad b_0 \neq 0$$

$$C(Z^{-1}) = 1 + c_1 Z^{-1} + \dots + c_n Z^{-n}$$

The self-tuning controller is designed to minimize the variance of an auxiliary output $\phi(t)$

$$\phi(t) = P(Z^{-1})Y(t) + Q(Z^{-1})U(t - K) - R(Z^{-1})W(t - K) \quad (4.6)$$

where $W(t)$ is the set point and P , Q and R are transfer functions of the forms

$$P(Z^{-1}) = \frac{P_n(Z^{-1})}{P_d(Z^{-1})}, \text{ etc} \quad (4.7)$$

If the process model in equation (4.5) is combined with the identity

$$CP_n = AP_dE + Z^{-K}F \quad (4.8)$$

where the degree of the polynomial F is given by

$$\deg F = n + \deg P_d - 1 \quad (4.9)$$

$$\text{and} \quad \deg E = K - 1 \quad (4.10)$$

The predictive model is obtained

$$\phi(t) = \frac{F}{P_d C} Y(t - K) + \left(\frac{EB}{C} + Q\right)U(t - K) - RW(t - K) + E\zeta(t) \quad (4.11)$$

A control law that minimizes the variance of $\phi(t)$ is given by

$$U(t) = \frac{CRW(t) - FY(t)/P_d}{EB + CQ} \quad (4.12)$$

An alternative predictive model is given by

$$\phi_y(t) = PY(t) \quad (4.13)$$

From equation (4.5) and equation (4.7), it follows that

$$\phi_y(t) = \frac{F}{P_d C} Y(t - K) + \frac{EB}{C} U(t - K) + E\zeta(t) \quad (4.14)$$

We set

$$G = EB \quad (4.15)$$

$$\text{and define } Y_f(t) = \frac{Y(t)}{P_d} \quad (4.16)$$

If we assume that $C = 1$, then linear least squares estimation can be used and the estimation model is given by

$$\phi_y(t) = FY_f(t - K) + GU(t - K) + \varepsilon(t) \quad (4.17)$$

Estimates of the elements of F and G can be obtained from the standard least squares equations. Thus the control law is given by

$$U(t) = \frac{RW(t) - FY_f(t)}{G + Q} \quad (4.18)$$

In order that the controller (4.18) may have a PID structure, the F polynomial is specified to have degree 2, i.e.

$$F = f_0 + f_1Z^{-1} + f_2Z^{-2} \quad (4.19)$$

and the output filter is $\deg P_d = 1$, i.e., $P_d = 1 + P_{d1}Z^{-1}$. Then from equation (4.9), we have $n = 2$, i.e. a second order process model.

As a final design step, R is set by

$$R = H_0 = \frac{f_0 + f_1 + f_2}{1 + P_{d1}} \quad (4.20)$$

and since Q may be freely chosen, integral action is introduced by setting

$$G + Q = \frac{1 - Z^{-1}}{V} \quad (4.21)$$

where V is a design parameter. Substituting equations (4.19), (4.20) and (4.21) into equation (4.18) yields controller

$$u(t) = V \{ H_0W(t) - (f_0 + f_1Z^{-1} + f_2Z^{-2})Y_f(t) \}$$

where $u(t) = (1 - Z^{-1})U(t) = U(t) - U(t-1)$

It is an ideal digital PID controller in velocity form [44].

4.3.2 - Self-Tuning PID Controllers Based on Zero/Pole Assignment [23]

The process model to be controlled is given by

$$Y(t) = z^{-1} \frac{B(z^{-1})}{A(z^{-1})} U(t) + \frac{C(z^{-1})}{A(z^{-1})} \zeta(t) \quad (4.22)$$

where $A(z^{-1}) = 1 + a_1 z^{-1} + a_2 z^{-2}$

$$B(z^{-1}) = b_0 + b_1 z^{-1} \quad ; \quad b_0 \neq 0$$

Time delay is not considered here.

Place the system in closed loop with an incremental controller given by equation (4.23), as shown in Fig. 4.3

$$u(t) = \frac{G(z^{-1})}{H(z^{-1})} e(t) \quad (4.23)$$

where $G(z^{-1}) = g_0 + g_1 z^{-1} + g_2 z^{-2}$

and $H(z^{-1}) = 1 + h_1 z^{-1}$

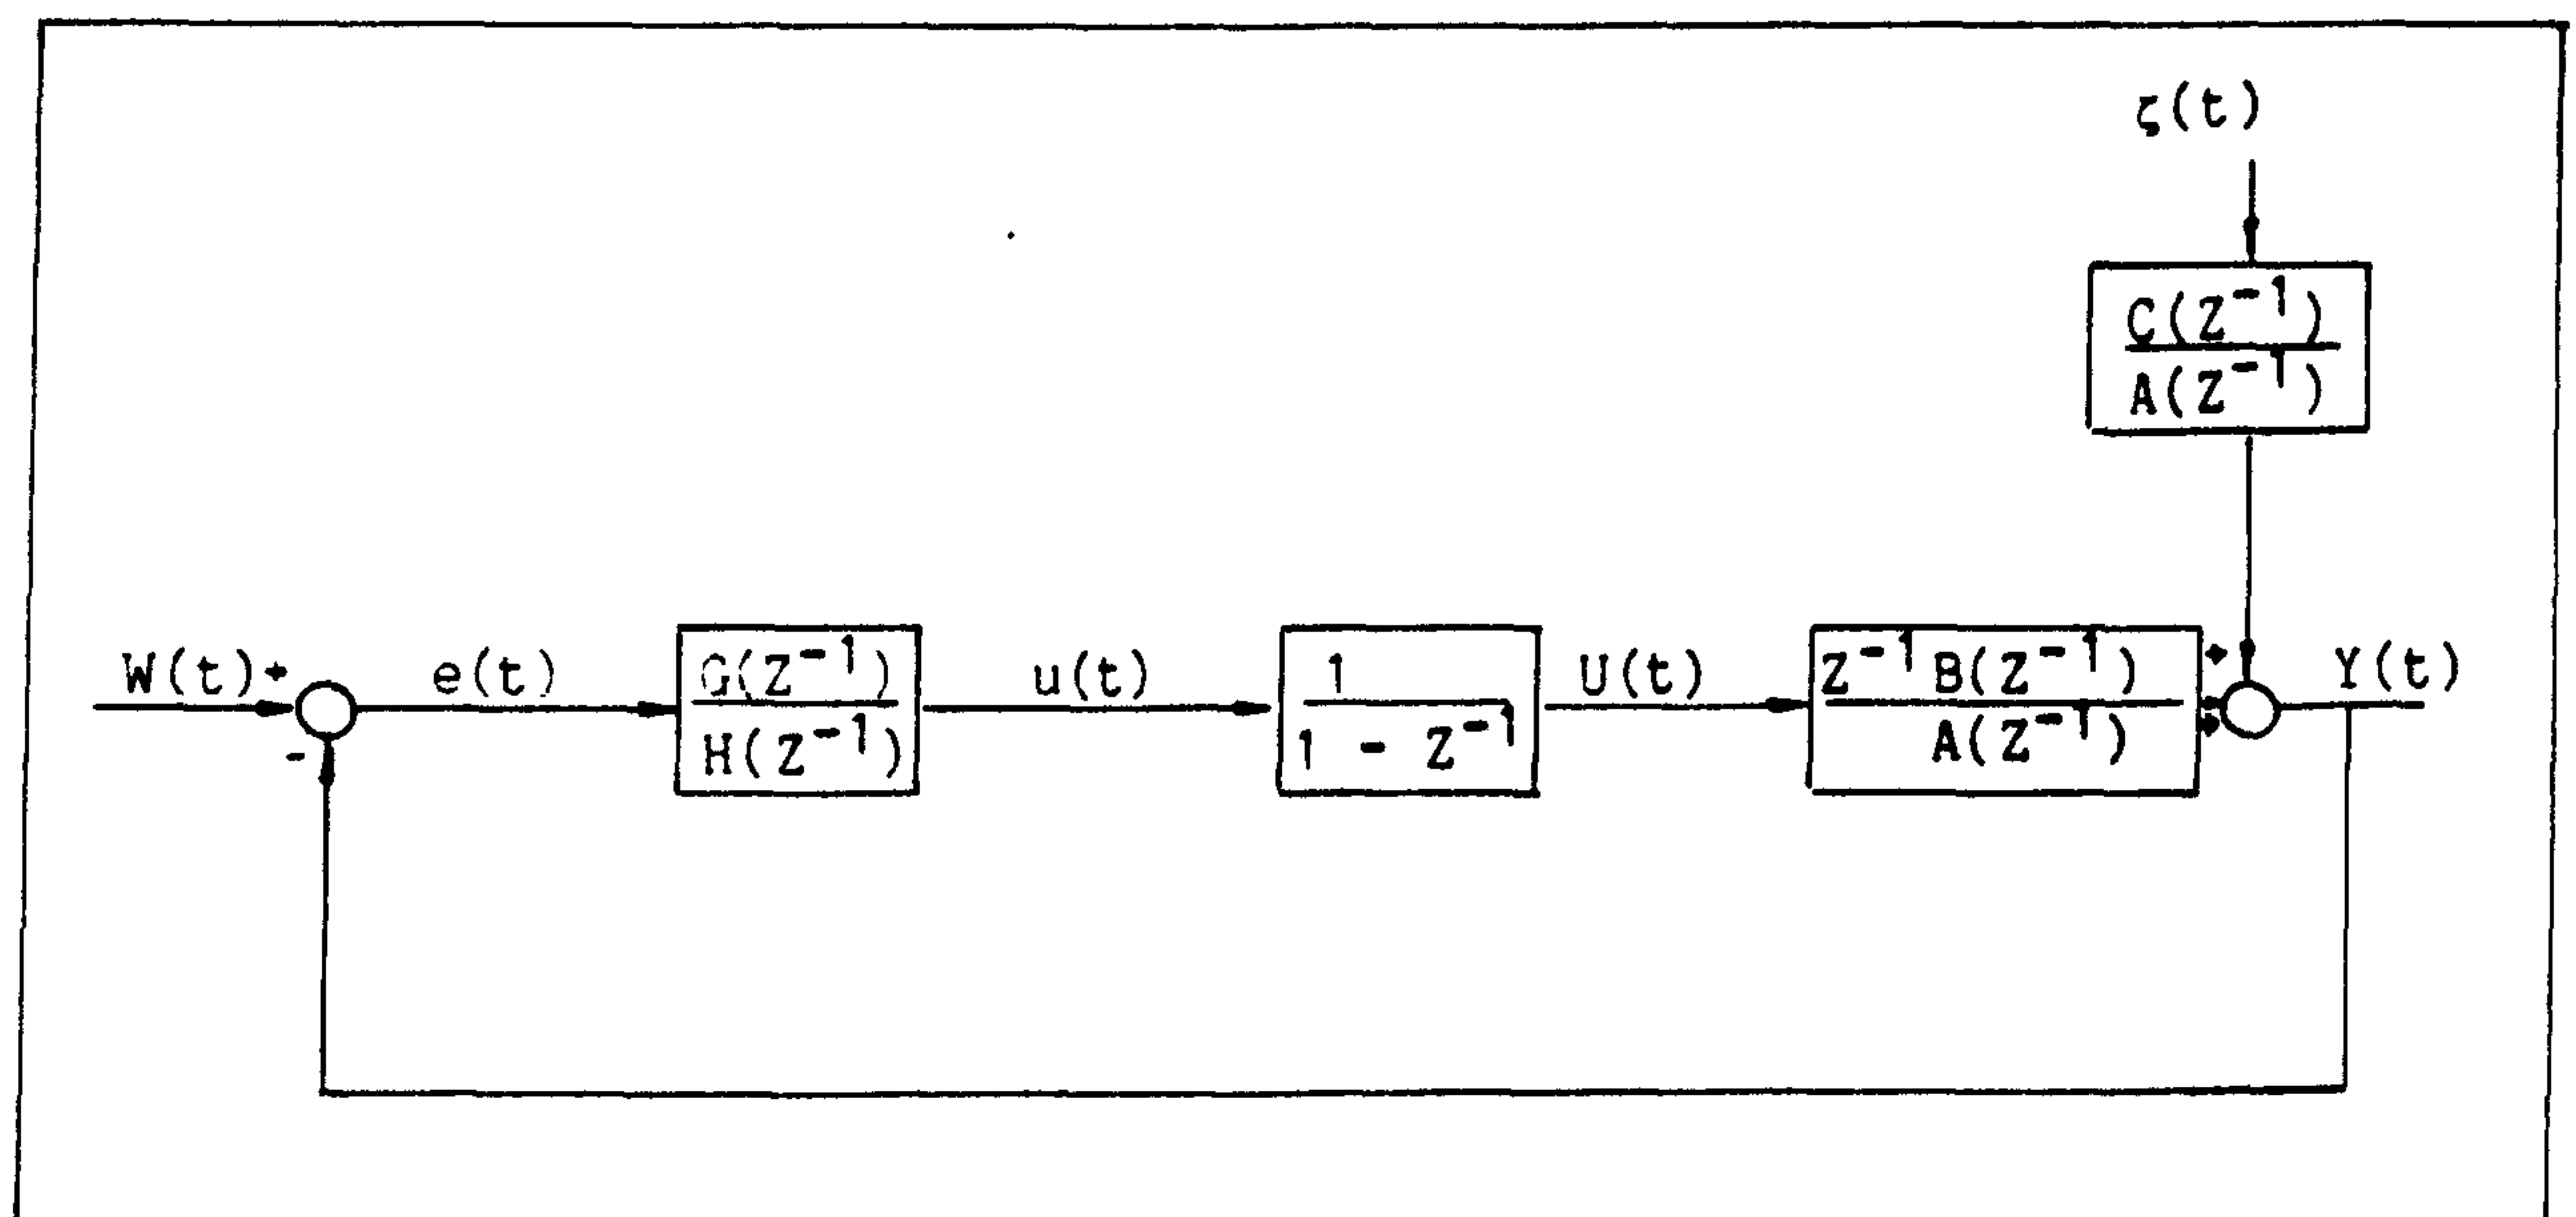

Fig. 4.3 Composite Servo/Regulator Configuration

Notice that a digital integrator is incorporated to ensure steady state correspondence between $Y(t)$ and $W(t)$ (stochastic regulator), or $Y(t)$ tracking of changes in $W(t)$ (servo-control). The closed-loop equation is given by

$$\begin{aligned} & \{(1-Z^{-1})A(Z^{-1})H(Z^{-1})+Z^{-1} B(Z^{-1})G(Z^{-1})\}Y(t) \\ & = Z^{-1} B(Z^{-1})G(Z^{-1})W(t)+C(Z^{-1})H(Z^{-1})\zeta(t) \end{aligned} \quad (4.24)$$

If the stochastic disturbance is negligible, then the servo tracking control law is found by solving the identity [45]

$$(1 - Z^{-1})A(Z^{-1})H(Z^{-1}) + Z^{-1}B(Z^{-1})G(Z^{-1}) = T(Z^{-1}) \quad (4.25)$$

for the unknown controller coefficients, where $T(Z^{-1})$ is a polynomial which defines the desired pole set. The regulator coefficients (stochastic regulator) are obtained by solving the identity

$$(1 - Z^{-1})A(Z^{-1})H(Z^{-1}) + Z^{-1}B(Z^{-1})G(Z^{-1}) = C(Z^{-1})T(Z^{-1}) \quad (4.26)$$

The self-tuning algorithm at each sample interval can be summarised as follows

- 1) Estimate the coefficients of the system model given by

$$Y(t) = -(a_1Z^{-1} + a_2Z^{-2})Y(t) + Z^{-1}(b_0 + b_1Z^{-1})U(t) + \epsilon(t) \quad (4.27)$$

- 2) Use the estimated data to synthesise the controller coefficients via the identities of equations (4.25) or (4.26).

- 3) Determine incremental $u(t)$ and apply the control $U(t)$ which is obtained by integrating $u(t)$ via a digital integrator.

Other different procedures of autotuning PID controllers also have been reported [23] [46] [47] [48]. In [46], a continuous-time self-tuning PID controller was proposed by Gawthrop. The integral action in this method arises naturally from a suitable model of disturbance rather than forcing integral action into the controller as in the previous two methods and a hybrid approach with a continuous-time model but discrete-time control law and estimation is used in the development of this method. Some commercial products with built-in PID self-tuners are available in the market [49] [50]. There is of no doubt that the provision of a procedure to automatically generate PID tuning constants instead of the usual trial-and-error method is very important in engineering practice.

4.4 - Design of Self-Tuning PID Controllers With Pole Assignment for Deterministic Systems

As mentioned before, self-tuning algorithms have been developed separately for the stochastic and deterministic cases. It has been shown that the basic self-tuning algorithm of the STC can be used correctly for deterministic systems; and pole assignment also can be incorporated as in [33] to provide pole assignment controllers focusing entirely on the servo or reference following problem.

The algorithm presented here shows that by inserting an integrator in the forward path, the self-tuning controller proposed in [35] has the same structure as a conventional three term PID controller (for second order systems) or PI controller (for first order systems). The major use of the resulting self-tuning PID controller for deterministic systems would be as an initial tuning device to determine the PID controller parameters needed to provide the specified control performance. Because deterministic system identification is only feasible under disturbance conditions, the controller set point will be suitably disturbed until convergence is achieved and the controller parameters then fixed until retuning is considered necessary. The tuning disturbance must be kept within the bounds acceptable to the plant.

In 4.4.1, the algorithm for deterministic systems is summarized, and in 4.4.2, it is shown how this leads to a self-tuning PID controller. The results of digital simulation and experiments are given in 4.4.3 and 4.4.4 respectively.

4.4.1 - Self-Tuning controllers for Deterministic Systems [35]

The system to be controlled is assumed to be described by

$$A(Z^{-1})Y(t) = Z^{-K}B(Z^{-1})U(t) \quad (4.28)$$

A controller of the following form is required

$$HU(t) + GY(t) - RW(t) = 0 \quad (4.29)$$

where H, G and R are polynomials in z^{-1} .

Introducing polynomials P and Q, and defining

$$PB + AQ = TR \quad \text{for } Q \neq 0 \quad (4.30)$$

$$\text{or } P = TR \quad \text{for } Q = 0 \quad (4.31)$$

Where T is the polynomial representing the desired closed-loop system poles, T and R are prespecified. Also, let polynomials F, G and H be defined from

$$P = AF + z^{-K}G \quad (4.32)$$

$$H = BF + Q \quad (4.33)$$

Combining equation (4.28) with equation (4.29) gives the closed-loop description

$$Y(t) = z^{-K} \frac{BR}{AH + z^{-K}BG} W(t) \quad (4.34)$$

Making use of equations (4.32) and (4.33), we have

$$AH + z^{-K}BG = BP + AQ \quad (4.35)$$

Then, using equations (4.30) and (4.31), equation (4.34) may be rewritten as

$$\begin{aligned} Y(t) &= \frac{z^{-K} BR}{PB + AQ} W(t) \\ &= \frac{z^{-K} B}{T} W(t) \quad \text{for } Q \neq 0 \end{aligned}$$

$$\text{or } Y(t) = \frac{z^{-K}}{T} W(t) \quad \text{for } Q = 0 \quad (4.36)$$

It gives a closed-loop system with the desired closed-loop transfer function.

Multiplying equation (4.35) by Y(t) and substituting for AY(t) from equation (4.28), equation (4.35) becomes

$$PY(t) + z^{-K}QU(t) = H z^{-K}U(t) + z^{-K}GY(t) \quad (4.37)$$

Equation (4.37) can be written as

$$\phi(t) = HZ^{-K}U(t) + Z^{-K}GY(t) \quad (4.38)$$

and
$$\phi(t) = PY(t) + Z^{-K}QU(t) \quad (4.39)$$

Equation (4.38) and equation (4.39) can be used to estimate the parameters of the polynomials H and G, and thus from equation (4.29) control U(t) can be determined.

4.4.2 - Self-Tuning PID Controllers With Pole Assignment for Deterministic Systems

The system is considered to be described by the equation (4.40)

$$Y(t) = Z^{-K} \frac{B}{A} U(t) + d \quad (4.40)$$

where U(t) and Y(t) are the system input and output respectively. A and B are polynomials in Z^{-1} , with $a_0 = 1$, d is a constant bias or off-set, and K represents the system time delay in sample instants.

If now an integrator is cascaded with the system, as in Fig. 4.4, the newly formed system can be expressed as

$$Y(t) = Z^{-K} \frac{B}{A'} u(t) + d \quad (4.41)$$

where $u(t) = (1 - Z^{-1})U(t) \quad (4.42)$

and $A' = (1 - Z^{-1})A$

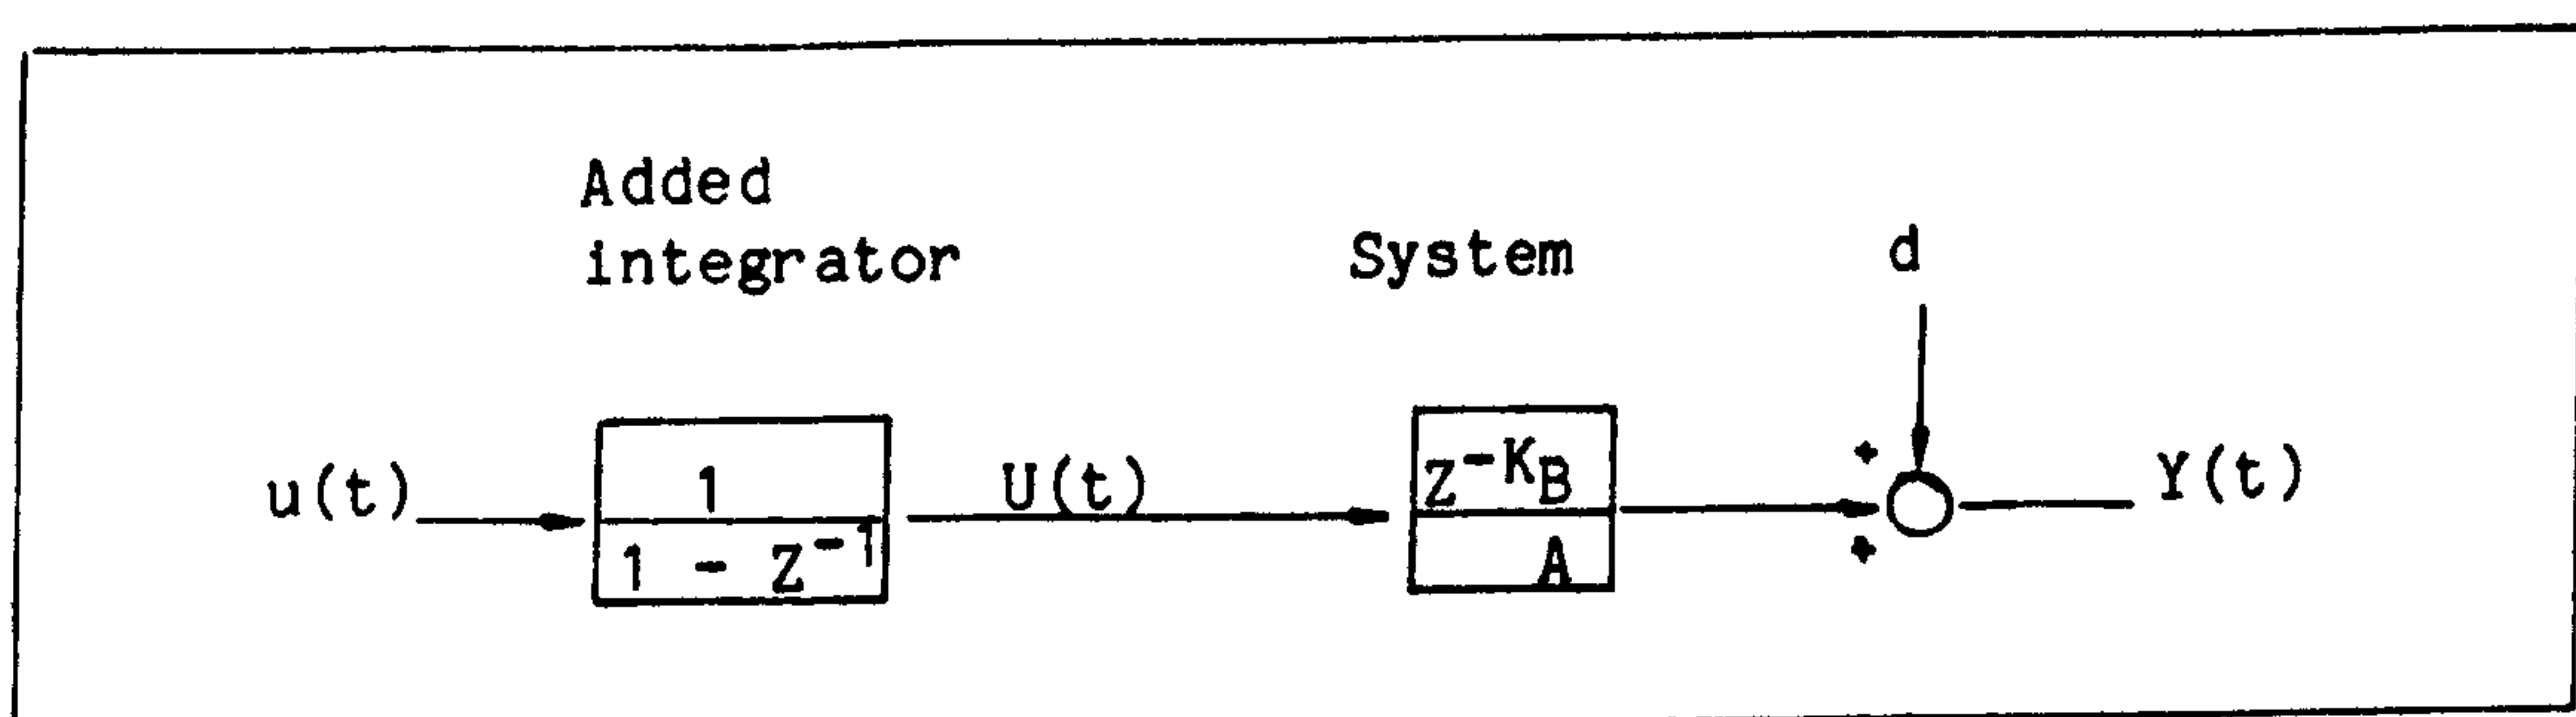

Fig. 4.4 Integrator Cascaded With System

In terms of the generalized minimum variance self-tuning strategy, a performance cost function $\phi(t)$ for the system can be defined as

$$\phi(t) = PY(t) + Qu(t-k) - RW(t-k) \quad (4.43)$$

Define polynomials F, G, E and H

$$P = FA' + Z^{-K}G \quad (4.44)$$

$$E = -R \quad (4.45)$$

$$H = BF + Q \quad (4.46)$$

Equations (4.41) to (4.46) may be combined to give

$$\phi(t) = Hu(t-k) + GY(t-k) + EW(t-k) + \delta \quad (4.47)$$

$$\text{where } \delta = (A'F) \bigg|_{Z=1} d \quad (4.48)$$

Thus the control law is given by

$$Hu(t) + GY(t) + EW(t) + \delta = 0 \quad (4.49)$$

Note that, since A' contains a factor $(1-Z^{-1})$, $\delta = 0$ from equation (4.48), and hence δ can be deleted from the estimation algorithm.

Rewriting equations (4.43), (4.47) and (4.49) gives

$$\phi(t) = PY(t) + Qu(t-k) - RW(t-k) \quad (4.50)$$

$$\phi(t) = Hu(t-k) + GY(t-k) + EW(t-k) \quad (4.51)$$

$$Hu(t) + GY(t) + EW(t) = 0 \quad (4.52)$$

Equations (4.50) and (4.51) may be written as

$$\phi(t) = PY(t) + Qu(t-k) \quad (4.53)$$

$$\phi(t) = Hu(t-k) + GY(t-k) \quad (4.54)$$

Equations (4.50), (4.51), or equations (4.53), (4.54) and equation (4.52) define a self-tuning control algorithm with an integrator operating on the system of equation (4.40).

A closed-loop description of the system may be obtained by substituting for $u(t)$ from equation (4.52) into equation (4.41)

$$Y(t) = \frac{Z^{-K} BR}{A'H + Z^{-K} BG} W(t) + \frac{A'H}{A'H + Z^{-K} BG} d \quad (4.55)$$

Since d is a constant bias and $A' = (1 - Z^{-1})A$, the second term in equation (4.55) vanishes and can therefore be eliminated. The added integrator therefore ensures that the bias does not influence the controller output.

Let P and Q be chosen such that:

$$BP + A'Q = T \quad (4.56)$$

where T is a prespecified polynomial in Z^{-1} whose roots are the desired values of the poles of the closed-loop transfer function. Substituting for P and H from equations (4.44) and (4.46) into equation (4.56) gives

$$BP + A'Q = A'H + Z^{-K}BG = T \quad (4.57)$$

Thus, the closed-loop transfer function is given by

$$Y(t) = \frac{Z^{-K}BR}{T} W(t) \quad (4.58)$$

For equations (4.44) and (4.57) to have a solution, the degrees of the polynomials P , Q , T , F , G and thus H (equation (4.46)) must be

$$\deg P = \deg A' - 1$$

$$\deg Q = \deg B - 1$$

$$\deg T \leq \deg A' + \deg B - 1$$

$$\deg F = k-1$$

$$\deg G = \deg A' - 1$$

$$\deg H = \deg B + K - 1 \quad (4.59)$$

When self-tuning, the system parameters A and B are unknown and hence equation (4.57) can not be solved directly to obtain the parameters of polynomials P and Q . However, multiplying equation (4.56) by F gives

$$FPB + QA'F = TF \quad (4.60)$$

Substituting for $A'F$ from equation (4.44) results in

$$FPB + QP - Z^{-K}GQ = TF \quad (4.61)$$

Further use of equation (4.46) gives

$$PH - Z^{-K} GQ = TF \quad (4.62)$$

In self-tuning control, the parameters H and G are identified recursively from equations (4.50) and (4.51) or equations (4.53) and (4.54). Then equation (4.62) may be solved to get the values for P and Q that will be used in the next step. Obviously for the first step, starting values for P and Q need to be assigned.

From equation (4.44), $p_0 = a_0' f_0$, but $a_0' = 1$, hence $p_0 = f_0$. p_0 may be set equal to unity, hence, $p_0 = f_0 = 1$. However, from equation (4.62) it can be seen that because h_0 is estimated freely from equation (4.51), the relationship $h_0 = t_0$ will not be satisfied. This problem can be avoided by modifying equation (4.62) as

$$PH - Z^{-K} GQ = h_0 FT \quad (4.63)$$

Similarly equation (4.56) becomes

$$BP + A'Q = h_0 T \quad (4.64)$$

Now for the second order system, $A(Z^{-1}) = 1 + a_1 Z^{-1} + a_2 Z^{-2}$, and $B(Z^{-1}) = b_0 + b_1 Z^{-1}$, from equation (4.59), $\deg G = 2$, $\deg H = 1$, i.e.

$$G(Z^{-1}) = g_0 + g_1 Z^{-1} + g_2 Z^{-2} \quad (4.65)$$

$$\text{and } H(Z^{-1}) = h_0 + h_1 Z^{-1} \quad (4.66)$$

From equation (4.52), the controller $u(t)$ is given by

$$u(t) = \frac{RW(t) - (g_0 + g_1 Z^{-1} + g_2 Z^{-2})Y(t)}{h_0 + h_1 Z^{-1}} \quad (4.67)$$

where $R = g_0 + g_1 + g_2$

Equation (4.67) gives the velocity form of the PID controller.

For the first order system, $A = 1 + a_1 Z^{-1}$, $B = b_0$, thus

$$G(Z^{-1}) = g_0 + g_1 Z^{-1} \quad (4.68)$$

$$H = h_0 \quad (4.69)$$

The controller is given by

$$u(t) = \frac{RW(t) - (g_0 + g_1 Z^{-1})Y(t)}{h_0} \quad (4.70)$$

It is the velocity form of PI controller.

In the foregoing discussion of synthesis procedures, a recursive estimation is needed to estimate the parameters of the controller, i.e. H and G. For a second order system with $K = 1$, equation (4.54) can be written in vector matrix format as

$$\phi(t) = Z^T(t)\theta + \varepsilon(t) \quad (4.71)$$

where $Z^T(t) = [u(t-1), u(t-2), y(t-1), y(t-2), y(t-3)] \quad (4.72)$

$$\theta^T(t) = [h_0, h_1, g_0, g_1, g_2] \quad (4.73)$$

and $\varepsilon(t)$ is the estimation error.

The recursive least square estimation of the vector of the controller coefficient θ at time interval t is given by [45]

$$\theta(t) = \theta(t-1) - P(t)Z(t)[Z^T(t)\theta(t-1) - \phi(t)] \quad (4.74)$$

$$P(t) = \overline{P(t-1)} - \overline{P(t-1)}Z(t)Z^T(t)\overline{P(t-1)}[1 + Z^T(t)\overline{P(t-1)}Z(t)] \quad (4.75)$$

where $\overline{P(t-1)} = P(t-1)/\rho \quad (4.76)$

ρ is an exponential forgetting factor and is used to make the controller follow time varying parameters. Its value is not less than 0.98 and not greater than 1.

At the time step $t = 1$, the initial matrices $P(0)$ and $\theta(0)$ must be specified. $\theta(0)$ can be set with guesses of coefficients, $P(0)$ can be set that $P(0) = \rho_0 I$, where ρ_0 is a large number, I is the unit matrix.

The algorithm is summarised as follows

1) Form $\phi(t) = PY(t) + Qu(t-k)$

Starting values for P and Q need to be assigned

2) Estimate H and G from $\phi(t) = Hu(t-k) + GY(t-k)$

3) Apply control $U(t) + GY(t) - RW(t) = 0$

4) Solve for P and Q from $PH - Z^{-K}GQ = h_0FT$

5) Repeat from 1) for the incremented value of t

The desired closed-loop pole-set is best specified in terms of either a first order or a second order polynomial in Z^{-1} [45]. For a first order response

$$T(Z^{-1}) = 1 + Z^{-1}t \quad (4.77)$$

where $t = -\exp(-T/\tau)$

T is the sampling period

τ is the desired closed-loop time constant, and typically $\tau = 3T$

For a second order system

$$\begin{aligned} T(Z^{-1}) &= 1 + Z^{-1}t_1 + Z^{-2}t_2 \\ t_1 &= -2 \exp(-\zeta\omega_n T) \cos(\omega_n \sqrt{1 - \zeta^2} T) \\ t_2 &= \exp(-2\zeta\omega_n T) \end{aligned} \quad (4.78)$$

where ω_n is the undamped natural frequency

ζ is the damping ratio of the corresponding continuous time second order characteristic polynomial, and typically $\omega_n \sqrt{1 - \zeta^2} T = 1/3$.

4.4.3 - Simulation and Results

A demonstration of how the self-tuning PID controller for deterministic systems works will be given in terms of simulated examples. The flowchart of the digital simulation program and the computer listing are given in Appendix 9.

Example 1

A second order system which is stable and minimum phase is considered having the system description

$$Y(t) = Z^{-1} \frac{1.57 + 1.36Z^{-1}}{1 - 1.628Z^{-1} + 0.657Z^{-2}} U(t) + d$$

Corresponding to the continuous-time system

$$G(s) = \frac{100}{(10s+1)(25s+1)}$$

with sampling period $T = 3$ second.

The aim is to have the closed-loop poles defined by

$T(Z^{-1}) = 1 - 1.47Z^{-1} + 0.604Z^{-2}$, corresponding to the continuous time second order characteristic polynomial with $\zeta = 0.6$, and $\omega_n = 0.14$.

Since polynomials A, B and T are known equations (4.44), (4.46) and (4.64) can be solved directly to find the required values of P, Q, H and G to which the self-tuning algorithm should converge, thus we have

$$\begin{aligned} h_0 &= \frac{b_0 a_2 + \frac{b_1^2}{b_0} - a_1 b_1 - \frac{a_3 b_0^2}{b_1}}{\frac{b_1 t_1}{b_0} + a_2 - t_2 - \frac{a_1 b_1}{b_0} - \frac{a_3 b_0}{b_1}} \\ q_0 &= h_0 - b_0 \\ p_2 &= -q_0 a_3 / b_1 \\ p_1 &= (h_0 t_1 + a_1 b_0 - a_1 h_0 - b_1) / b_0 \\ h_1 &= b_1 \\ g_0 &= p_1 - a_1 \\ g_1 &= p_2 - a_2 \\ g_2 &= -a_3 \end{aligned} \tag{4.79}$$

Substituting for the parameters of the system into equation (4.79), we have

$$\begin{aligned} P &= 1 - 1.58Z^{-1} + 0.58Z^{-2} \\ Q &= 1.2 \\ G &= 1.18 - 1.71Z^{-1} + 0.657Z^{-2} \\ H &= 2.77 + 1.36Z^{-1} \end{aligned}$$

Define the parameter set $\theta = (h_0, h_1, g_0, g_1, g_2)$, then the parameter set θ_{true} which satisfies the required control constraint is given by $\theta_{\text{true}} = (2.77, 1.36, 1.18, -1.71, 0.657)$. In this case, offset $d = 1$, the algorithm is started with initial values of $P = 1$, $Q = 0$ and

$\theta_{\text{initial}} = (0.8, 0.4, 0.4, -0.4, 0.2)$. Fig. 4.5 shows the system reference input, output, system control $U(t)$, the parameters of $Q = q_0$, $H(Z^{-1}) = h_0 + h_1 Z^{-1}$ and $G(Z^{-1}) = g_0 + g_1 Z^{-1} + g_2 Z^{-2}$. As can be seen, all the parameters converge to the expected values. It should be noted that, when $\theta_{\text{initial}} = (0.5, 0.36, 0.4, -0.4, 0.1)$, the estimation tended to diverge.

Example 2

In this case, the situation is the same as in example 1, but the desired closed-loop poles are defined by $T(Z^{-1}) = 1 - 1.2Z^{-1} + 0.41Z^{-2}$, corresponding to the continuous time second order characteristic polynomial with $\zeta = 0.8$, $\omega_n = 0.19$. Fig. 4.6 shows the system output. Fig. 4.7 and Fig. 4.8 show the system outputs, if the desired closed-loop poles are defined by $T(Z^{-1}) = 1 - 1.2Z^{-1} + 0.604Z^{-2}$ and $T(Z^{-1}) = 1 - 0.82Z^{-1} + 0.41Z^{-2}$ respectively.

Example 3

The system to be considered is given by

$$Y(t) = \frac{0.48Z^{-1}}{1 - 0.91Z^{-1}} U(t) + d$$

corresponding to the continuous-time system

$$G(s) = \frac{5}{1 + 0.1s}$$

with sampling period $T = 0.01$ second. The desired closed-loop pole is defined by $T(Z^{-1}) = 1 - 0.517Z^{-1}$. The algorithm is started with initial values of $P = 1$ and $\theta_{\text{initial}} = (0.1, 0.2, -0.2)$. Fig. 4.9 shows the system output and the parameter of h_0 , it can be seen that, h_0 converges to its expected value $h_0 = b_0 = 0.48$.

Fig. 4.9b System Response and Parameter Convergence for Example 3

Example 4

In this case, a system which is a stable and nonminimum phase second order system is to be considered [52]

$$Y(z) = \frac{z^{-1}(-0.0231 + 0.0745z^{-1})}{1 - 1.535z^{-1} + 0.587z^{-2}} U(z) + d$$

corresponding to the continuous-time system

$$G(s) = \frac{-s + 1}{(3s + 1)(5s + 1)}$$

with samples every second.

The algorithm is started with initial values of $P = 1$, $Q = 0$ and $\theta_{\text{initial}} = (0.014, 0.03, 0.5, -0.8, 0.2)$. The desired closed-loop poles are defined by $T(z^{-1}) = 1 - 1.2z^{-1} + 0.41z^{-2}$, corresponding to the continuous time second order characteristic polynomial with $\zeta = 0.8$ $\omega_n = 0.56$. Fig. 4.10 shows the system output and the parameter of q_0 . Fig. 4.11 shows the system output and the parameter of q_0 , if $T(z^{-1}) = 1 - 1.04z^{-1} + 0.52z^{-2}$.

When $\theta_{\text{initial}} = (0.005, 0.01, 0.2, -0.5, 0.1)$, the estimation tended to diverge.

 $T(Z^{-1}) = 1 - 1.04Z^{-1} + 0.52Z^{-2}$

4.4.4 - Experiments and Results

The behaviour of the self-tuning PID controller has been tested in several experimental applications. The control algorithm was implemented using a 16-bit MC 68000 single board computer which was interfaced to the controlled system. The control algorithm was written in assembly language. For 16-bit fixed-point arithmetic, the program required less than 1.2k-bytes of RAM for the control program itself and 0.25k-bytes of RAM to store intermediate values. The total computation time for this program was less than 12 ms. Except for some very fast processes, this time was acceptable. However, the 16-bit configuration limited the accuracy of computation.

To improve the accuracy of computation, software was rewritten in 24-bit floating-point arithmetic. This version required 2k-bytes of RAM, of which about 0.5k-bytes were required for storing intermediate values. The total computation time was about 100 ms.

The programs for both fixed-point and floating-point arithmetic and their brief specifications are given in Appendix 10.

Experiment 1

The process in this case is an analogue simulator and the configuration of the control system is shown in Fig. 4.12.

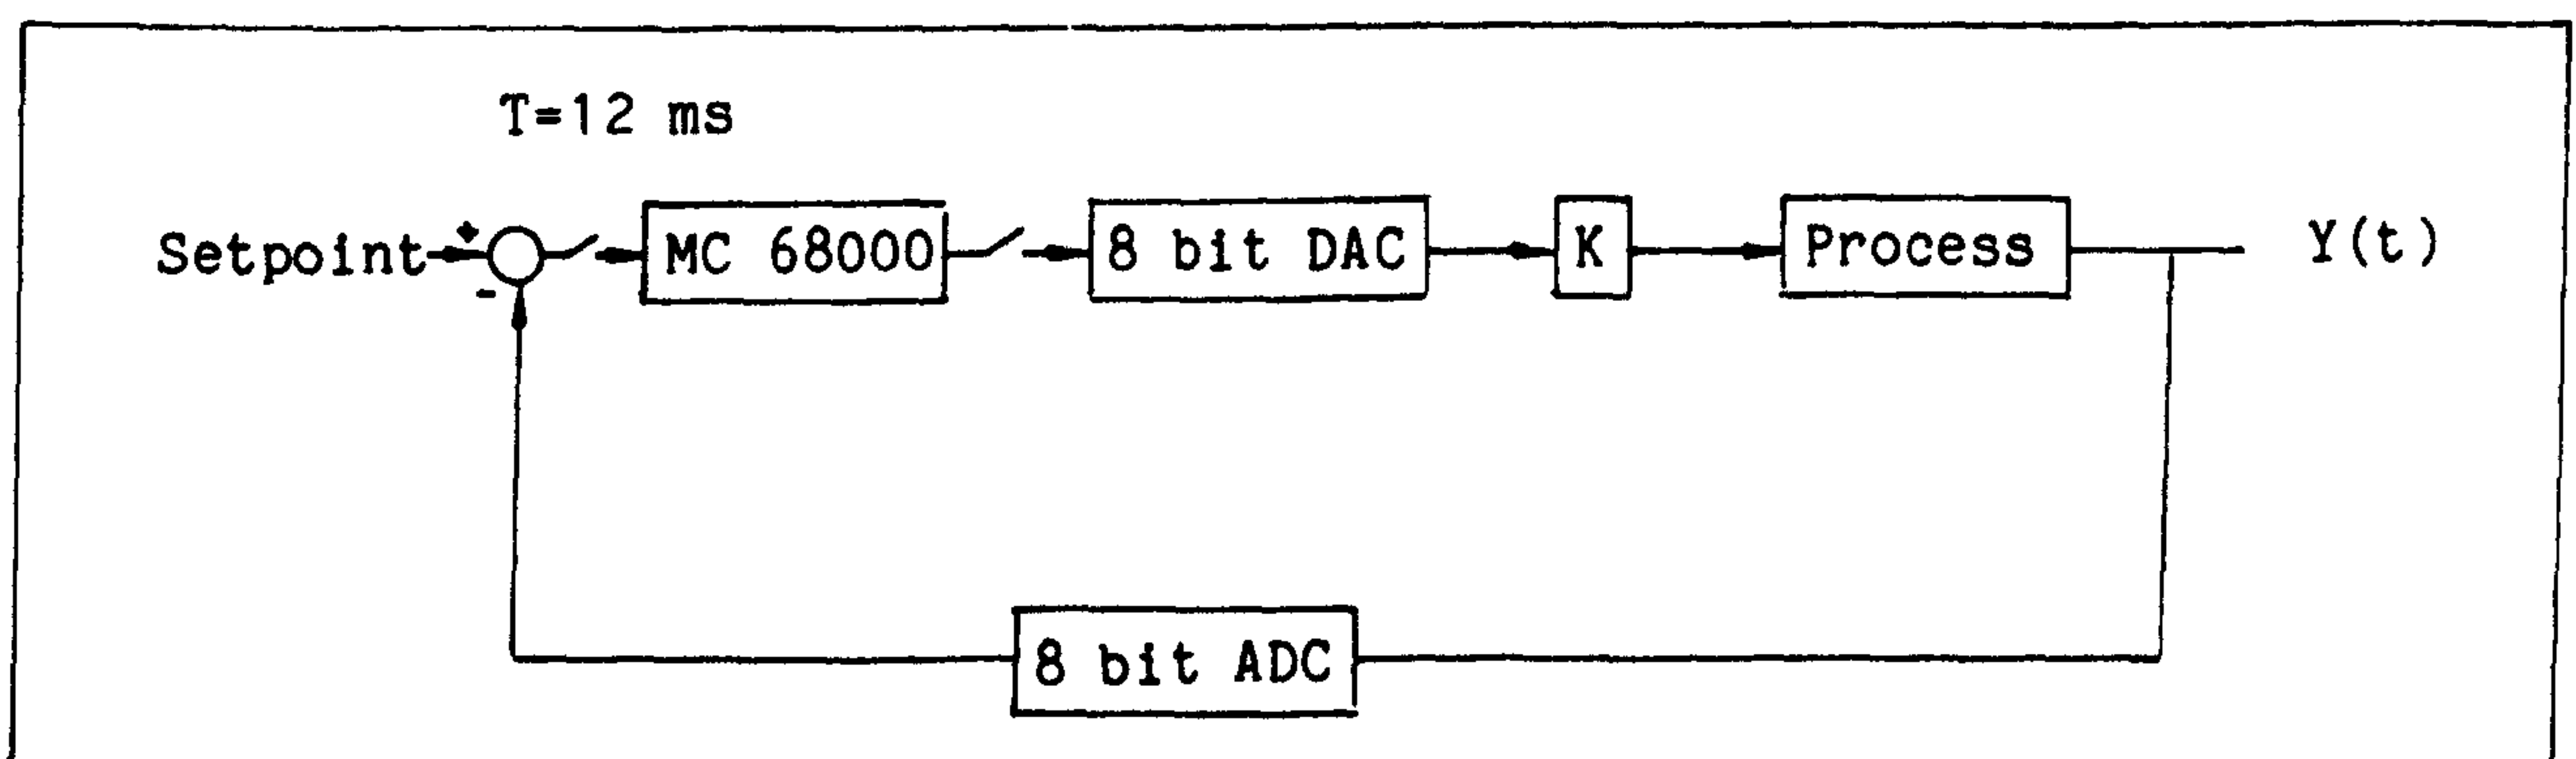

Fig. 4.12 Block Diagram of the Process Control System

The open-loop step response of the process is shown in Fig. 4.13, and from which the transfer function of the process is approximately given by

$$G(s) = \frac{K}{(1+0.064s)(1+0.015s)}$$

and

$$G(z^{-1}) = \frac{z^{-1}(0.052 + 0.042 z^{-1})}{1 - 1.28z^{-1} + 0.374z^{-2}}$$

with sampling period 12 ms.

Since polynomials A and B are known, equation (4.79) can be solved directly to find the values of the controller parameters which satisfy the required control constraint. Thus we have

$$\theta_{\text{true}} = (0.103, 0.042, 1.0, -1.2, 0.374)$$

with

$$T(z^{-1}) = 1 - 1.363z^{-1} + 0.52z^{-2}$$

The flowchart for the control algorithm implemented on the MC 68000 is shown in Fig. 4.14. In this case, the program ran continuously in a loop and the computation time was about 11.5 ms. The initial value of ρ_0 was taken equal to 128 (7FFF Hex with 7 bit integer and 8 bit fraction). The setpoint was periodically changed by the program from 0.08 to 0.47 (maximum value is equal to 1) for every 20 sampling periods, i.e. 0.23 s, as a system disturbance input for the estimation procedure. In actual process control, as soon as convergence was achieved, the estimation and the disturbance as well should be terminated and then the controller parameters would be fixed at the estimated values. Here, after 150 sampling periods, the estimation procedure was interrupted by the program itself and then the estimated data were read out.

Fig. 4.15 shows the system output during the estimation procedure. Table 1 lists 6 sets of estimated values of θ and the values of matrix $P(t)$ when the estimation procedure finishes. The estimation started with

initial values of $P(Z^{-1}) = 1$, $Q(Z^{-1}) = 0$ and

$\theta_{\text{initial}} = (0.063, 0.0468, 1.344, -1.61, 0.375)$ and the control constraint was given by $T(Z^{-1}) = 1 - 1.363Z^{-1} + 0.52Z^{-2}$.

Fig. 4.16 shows the closed loop step responses of the system with the controller parameters of

$\theta_{\text{initial}} = (0.063, .0468, 1.344, -1.61, 0.375)$ and

$\theta = (0.078, 0.027, 1.18, -1.35, 0.43)$. Experiments showed that with $\theta_{\text{initial}} = (0, 0, 0, 0, 0)$, the convergence of the estimation process became very poor.

----------	--

Table 4.1 Estimated Values and Matrix P(t)

Fig. 4.16 Step Response of the Closed-loop System

Experiment 2

The configuration of the control system is shown in Fig. 4.12, but the process is a hydraulic motor system and the sampling period is 12 ms.

The continuous time transfer function of the process is approximately given by

$$G(s) = \frac{e^{-0.012s}}{(0.06s+1)(0.01s+1)}$$

The flowchart of the estimation algorithm is shown in Fig. 4.17 and the program execution was interrupt driven. In this case, at the commissioning stage a fixed parameter PID controller was used to control the process directly and the setpoint was suitably disturbed. The outputs of the process and the controller were used to estimate the parameters for the self-tuning PID controller. The self-tuning PID controller itself did not generate a control signal. When convergence was achieved, the estimated values were transmitted to the PID controller. Then the parameters were fixed until retuning was considered necessary. Fig. 4.18 shows the system output at the commissioning stage. However, in this experiment at point "a" (Fig. 4.18), the computation was interrupted by the program and then the estimated values were read out. Table 4.2 lists some estimated values with initial values of $\theta = (0.2, 0.01, 1.6, -1.7, 0.4)$, and control constraint $T(Z^{-1}) = 1 - 1.2Z^{-1} + 0.41Z^{-2}$

It was found that in order to have better estimation results, at the commissioning stage, the range of the disturbance at the setpoint and the estimation times should reach certain values. Experiments also showed that the controller fixed with the estimated values listed in Table 4.2 gave rise to a poor response (seriously overdamped). In order to obtain a good performance, the estimated values in Table 4.2 had to be

modified.

Fig. 3.30 (p.103) shows the closed loop response of the system with the controller whose parameters are those estimated with some modification, i.e., $\theta = (0.3, 0.19, 1.33, -1.37, 0.125)$. It is judged that, because of dead time in the process, the discrepancy between the model needed for this algorithm and the actual process model causes the behaviour of the estimated parameters to be poor.

Table 4.2 Some Estimated Values

Experiment 3

For this experiment, a temperature platform was used, being able to provide a temperature range from room temperature up to 80°C.

Temperature control was achieved by varying the average output voltage of the associated power supply. A temperature sensor was used to detect the platform temperature. The configuration of the control system is shown in Fig. 4.12.

From the open loop step response of the process as shown in Fig. 4.19, the transfer function of the process is given by

$$G(s) = \frac{1}{1 + \tau s}$$

where $\tau = 840$ second

and
$$G(z^{-1}) = \frac{b_0}{1 - a_0 z^{-1}}$$

where $b_0 = 0.0465$, $a_0 = 0.954$, with sampling period 40 second.

From equation (4.79), the parameters of the PI controller are given by Table 4.3.

$T = 1-0.6Z^{-1}$	$\theta_{true} = (0.0465, 1.354, -0.954)$
$T = 1-0.7Z^{-1}$	$\theta_{true} = (0.0465, 1.254, -0.954)$
$T = 1-0.8Z^{-1}$	$\theta_{true} = (0.0465, 1.154, -0.954)$

Table 4.3

The flowchart of the estimation algorithm is the same as in experiment 2. Fig. 4.20 shows the system reference input sequence and output under the periodic setpoint change as system disturbance input at commissioning stage. Table 4.5 gives some estimation results with different initial values and the values of the matrix $P(t)$ when the estimation procedure finishes. The commisioning stage is about 100 sampling periods, i.e., 4000 second. Experiments showed that parameters converged to their expected values with very high repeatability.

Closed loop pole	Estimated Values
$T = 1-0.6Z^{-1}$	$\theta = (0.037, 1.34, -1.04)$
$T = 1-0.7Z^{-1}$	$\theta = (0.036, 1.29, -1.09)$
$T = 1-0.8Z^{-1}$	$\theta = (0.04, 1.24, -1.13)$
Initial Values $\theta = (0.1, 0.4, -2)$

4.5 - Discussion and Conclusion

Discussion

The experimental applications of the self-tuning PID controller have indicated that it is not entirely straightforward to use this kind of controller. There are many precautions that must be taken and also it is important to have as much a prior knowledge about the process as possible. The initial values of the parameters to be estimated must be prespecified with care otherwise the estimation will diverge. So if the process has been controlled before with a conventional controller, the initial values should be such that they correspond to the controller used before. The system set point also should be suitably disturbed in order to have a proper conditioning of signals which will give rise to a good convergence.

Although the 12 ms operation time of fixed-point arithmetic is acceptable for many fast processes, including large electrical and hydraulic drive systems, the accuracy of the computation limits its application in cases where unusually high accuracy is desired. The 100 ms operation time of floating-point arithmetic is acceptable for some fairly slow process, such as temperature, flow, level, etc, with very high operational accuracy, thereby resulting in better performance with the controller. Therefore this floating-point algorithm can be recommended to tune a PID controller either as an initial tuning device, or when required, provided that the model of the process is suitable.

When a process exhibits large apparent dead-time characteristics, the self-tuning PID algorithm is no longer suitable for this model, and like a conventional PID controller, it does not work very well. However, other self-tuning controllers can improve this situation.

Conclusion

A self-tuning PID controller with pole assignment for a deterministic process has been presented and investigated in this chapter. The algorithm proposed here is the same as the self-tuning controller for deterministic systems [35], but an integrator is incorporated into the control loop, which results in a self-tuning controller with PID structure. As we are dealing with a deterministic system, an implicit algorithm can be used. But control system identification is only feasible under disturbed conditions.

The algorithm has been implemented on the MC 68000 with both 16-bit fixed-point and 24-bit floating-point arithmetics. It has been shown that the algorithm can be easily implemented on a microcomputer system or on single board computers. Experimental applications have indicated that the floating-point algorithm performs well and can be used in industrial applications.

The major use of the controller proposed here would be as an initial tuning device to determine the controller parameters, or to allow the the controller to track the operating conditions of the slowly time-varying or non-linear process under control.

CHAPTER 5 : Conclusion and Recommendations for Future Work

5.1 - Conclusion

An analysis of the dieless wire drawing process, based on Non-Newtonian fluid behaviour of the polymer melt, has been developed. The effect of the thermal energy generated by viscous "friction" in the wire drawing process has been taken into consideration by coupling the energy equation into the analysis and assuming the polymer viscosity to be dependent on temperature. The theoretical results in terms of predicting the deformation profile, the pressure distribution within the DRU and the drawing load during the drawing process, agreed very well with those observed experimentally. An extensive experiment has been carried out, in which parameters such as drawing speeds, the temperature of the polymer melt and type of polymers were varied.

Based on the theoretical and experimental results, a microcomputer-based control system for the dieless wire drawing process has been designed and constructed in order to produce wires of desired qualities. A method detecting the PRA of the wire during the drawing process was proposed. The PRA indicator worked well under steady-state conditions, but fluctuation in readings occurred under transient conditions.

The qualities of the wire of a uniform diameter drawn by the new drawing system were found to be comparable to those drawn by using the conventional drawing process. Tapered wire of a uniform change in area with a desired rate for a given length was produced. The error in the PRA of the produced wires was within the range of ± 2 percent.

A self-tuning PID controller with pole assignment for deterministic systems has been proposed and investigated. An implicit algorithm was used and the control system identification was only feasible under

disturbed conditions. The algorithm has been implemented on the MC68000 microcomputer with both 16-bit fixed-point and 24-bit floating-point arithmetics. Experimental applications indicated that the floating-point algorithm performed well and could be used in practical applications. The major use of the controller is as an initial tuning device to determine the controller parameters, or to provide an adaptive control system in which the PID controller parameters are modified to adapt to a changing situation.

5.2 - Recommendations for Future Work

In the theoretical analysis of the dieless wire drawing process, the amount of heat generated from the deformation of the wire needs to be taken into consideration to further improve the theoretical results. Since the apparent viscosity of the polymer melt is a function of the temperature of the polymer melt and the pressure within the DRU, the viscosity of the polymer melt can be described by

$$\mu = \mu_0 e^{-aT + bP}$$

Where b is the viscosity pressure dependency constant. However, with this equation introduced into the analysis, the analysis will become much more complicated than the present one.

10-bit ADC and DAC converters can be used to increase the accuracy of the dieless wire drawing speed control system, and as a result of this, the quality of the produced wire will be improved. To enable a closed-loop control system with good performance to be built using the PRA as a feedback signal, the mechanical components of the PRA transducer require some improvement.

The commissioning stage of the self-tuning PID controller for deterministic systems is only feasible under disturbance condition, and the controller setpoint will be suitably disturbed until the

identification convergence is achieved. The controller parameters will then be fixed until retuning is considered necessary. Here several questions arise as to when this controller can be actually applied. What is the magnitude of the "suitable disturbance" which needs to be added into the input of the controller at the commissioning stage? How much time must elapse (how many time steps of the on line identification algorithm) for the identification to reach convergence? How can we judge a proper set of parameters of the controller has been estimated? To have the solutions of these questions, there is still some work to be done both in theory and practice.

Appendix 1 : Viscosity-Temperature Dependence of the Polymer Melt [10]

For many polymers at temperatures considerably above their glass-transition temperature, the melt viscosity has been experimentally determined to be an exponential function of the absolute temperature as given by the Arrhenius-type equation

$$\mu = A \exp (\Delta E / RT) \quad (A1.1)$$

where μ is the melt viscosity of the polymer

R a constant

A a frequency term

ΔE the energy of activation

A and ΔE must be evaluated empirically for each polymer. In addition to the variation of ΔE and A from polymer to polymer, A and ΔE are also the function of shear rate or shear stress.

The data [11] indicating the temperature dependence of melt viscosity at constant stress and pressure are presented in Fig. 2.11. It can be seen from Fig. 2.11 that, for low density polyethylene, increasing the temperature by 40°C decreases the viscosity at constant stress and constant pressure by a factor of about 3. The melt viscosity-temperature dependence resulting from Fig. 2.11 could be expressed by

$$\mu = \mu_0 e^{-aT} \quad (A1.2)$$

where " a " is a constant for a given polymer and its value is within the range from 0.02 to 0.1 . μ_0 is the initial viscosity at reference temperature.

However, for many polymers, ΔE (equation A1.1), or " a " (equation A1.2) is a function of temperature. For such polymers, Williams, Landel and Ferry [10] showed that the reduced viscosity data

for a wide variety of polymers could be expressed by the universal WLF equation

$$\mu = \mu_s \exp \left[- \frac{8.86(T - T_s)}{101.6 + T - T_s} \right]$$

where T_s is the reference temperature

μ_s is the viscosity at the reference temperature

The WLF equation is applicable over the temperature range of T_s+50° .

An alternative equation of viscosity-temperature dependence is given by

$$\mu = \mu_{T_g} \exp \left[\frac{-17.44(T - T_g)}{51.6 + T - T_g} \right]$$

where T_g is the glass-transition temperature of the polymer

μ_{T_g} is the melt viscosity at temperature T_g

In general, the WLF equation begins to fail as a valid representation of the viscosity-temperature dependence in the temperature region of T_g+100° , and in some high region the behavior becomes Arrhenius in form.

In theoretical analysis equation (A1.2) is particularly amenable to mathematical treatment.

Appendix 2 : A Integration Formula

The integral region R of the double integral

$$\int_0^{h_1} \int_0^Y f(Y') dY' dY$$

can be described by inequalities of the form $0 \leq Y \leq h_1$
and $0 \leq Y' \leq Y$ (Fig. A2.1). R also can be described by inequalities
of the form $0 \leq y' \leq h_1$ and $Y' \leq y \leq h_1$. Then we obtain

$$\begin{aligned} \int_0^{h_1} \int_0^Y f(Y') dY' dY &= \int_0^{h_1} \int_{Y'}^{h_1} f(Y') dY dY' \\ &= \int_0^{h_1} (h_1 - Y') f(Y') dY' \end{aligned}$$

Fig. A2.1

Appendix 3 : Energy Equation Applied to the Process of Dieless Wire Drawing

For incompressible flow, the energy equation is given by [12]

$$\rho c \bar{u} \nabla T = k \nabla^2 T + R \quad (A3.1)$$

where ρ is the melt density

c the specific heat

\bar{u} the velocity vector

R the volumetric rate of heat generation

k the thermal conductivity

T the temperature

∇T the temperature gradient

$\nabla^2 T$ the temperature divergence.

Now consider applying the energy equation to process of the dieless wire drawing as sketched in Fig. 2.1a (p. 16). For viscous heating with a Newtonian fluid

$$R = \mu \left(\frac{\partial u}{\partial Y} \right)^2 = \tau \dot{\epsilon} \quad (A3.2)$$

where $\dot{\epsilon}$ is the strain rate. In two dimensions we have

$$\bar{u} = u \mathbf{i} \quad (A3.3)$$

(assuming the flow of the polymer melt is axial)

$$\text{and} \quad \nabla T = \frac{\partial T}{\partial X} \mathbf{i} + \frac{\partial T}{\partial Y} \mathbf{j} \quad (A3.4)$$

$$\nabla^2 T = \frac{\partial^2 T}{\partial X^2} + \frac{\partial^2 T}{\partial Y^2} \quad (A3.5)$$

Substituting for R , u , ∇T and $\nabla^2 T$ from equations (A3.2) to (A3.5) respectively in equation (A3.1) gives

$$\rho c u \frac{\partial T}{\partial X} = k \left[\frac{\partial^2 T}{\partial X^2} + \frac{\partial^2 T}{\partial Y^2} \right] + \mu \left(\frac{\partial u}{\partial Y} \right)^2 \quad (A3.6)$$

Let

$$X' = X / L_1$$

$$Y' = Y / h$$

$$u' = u / u_0$$

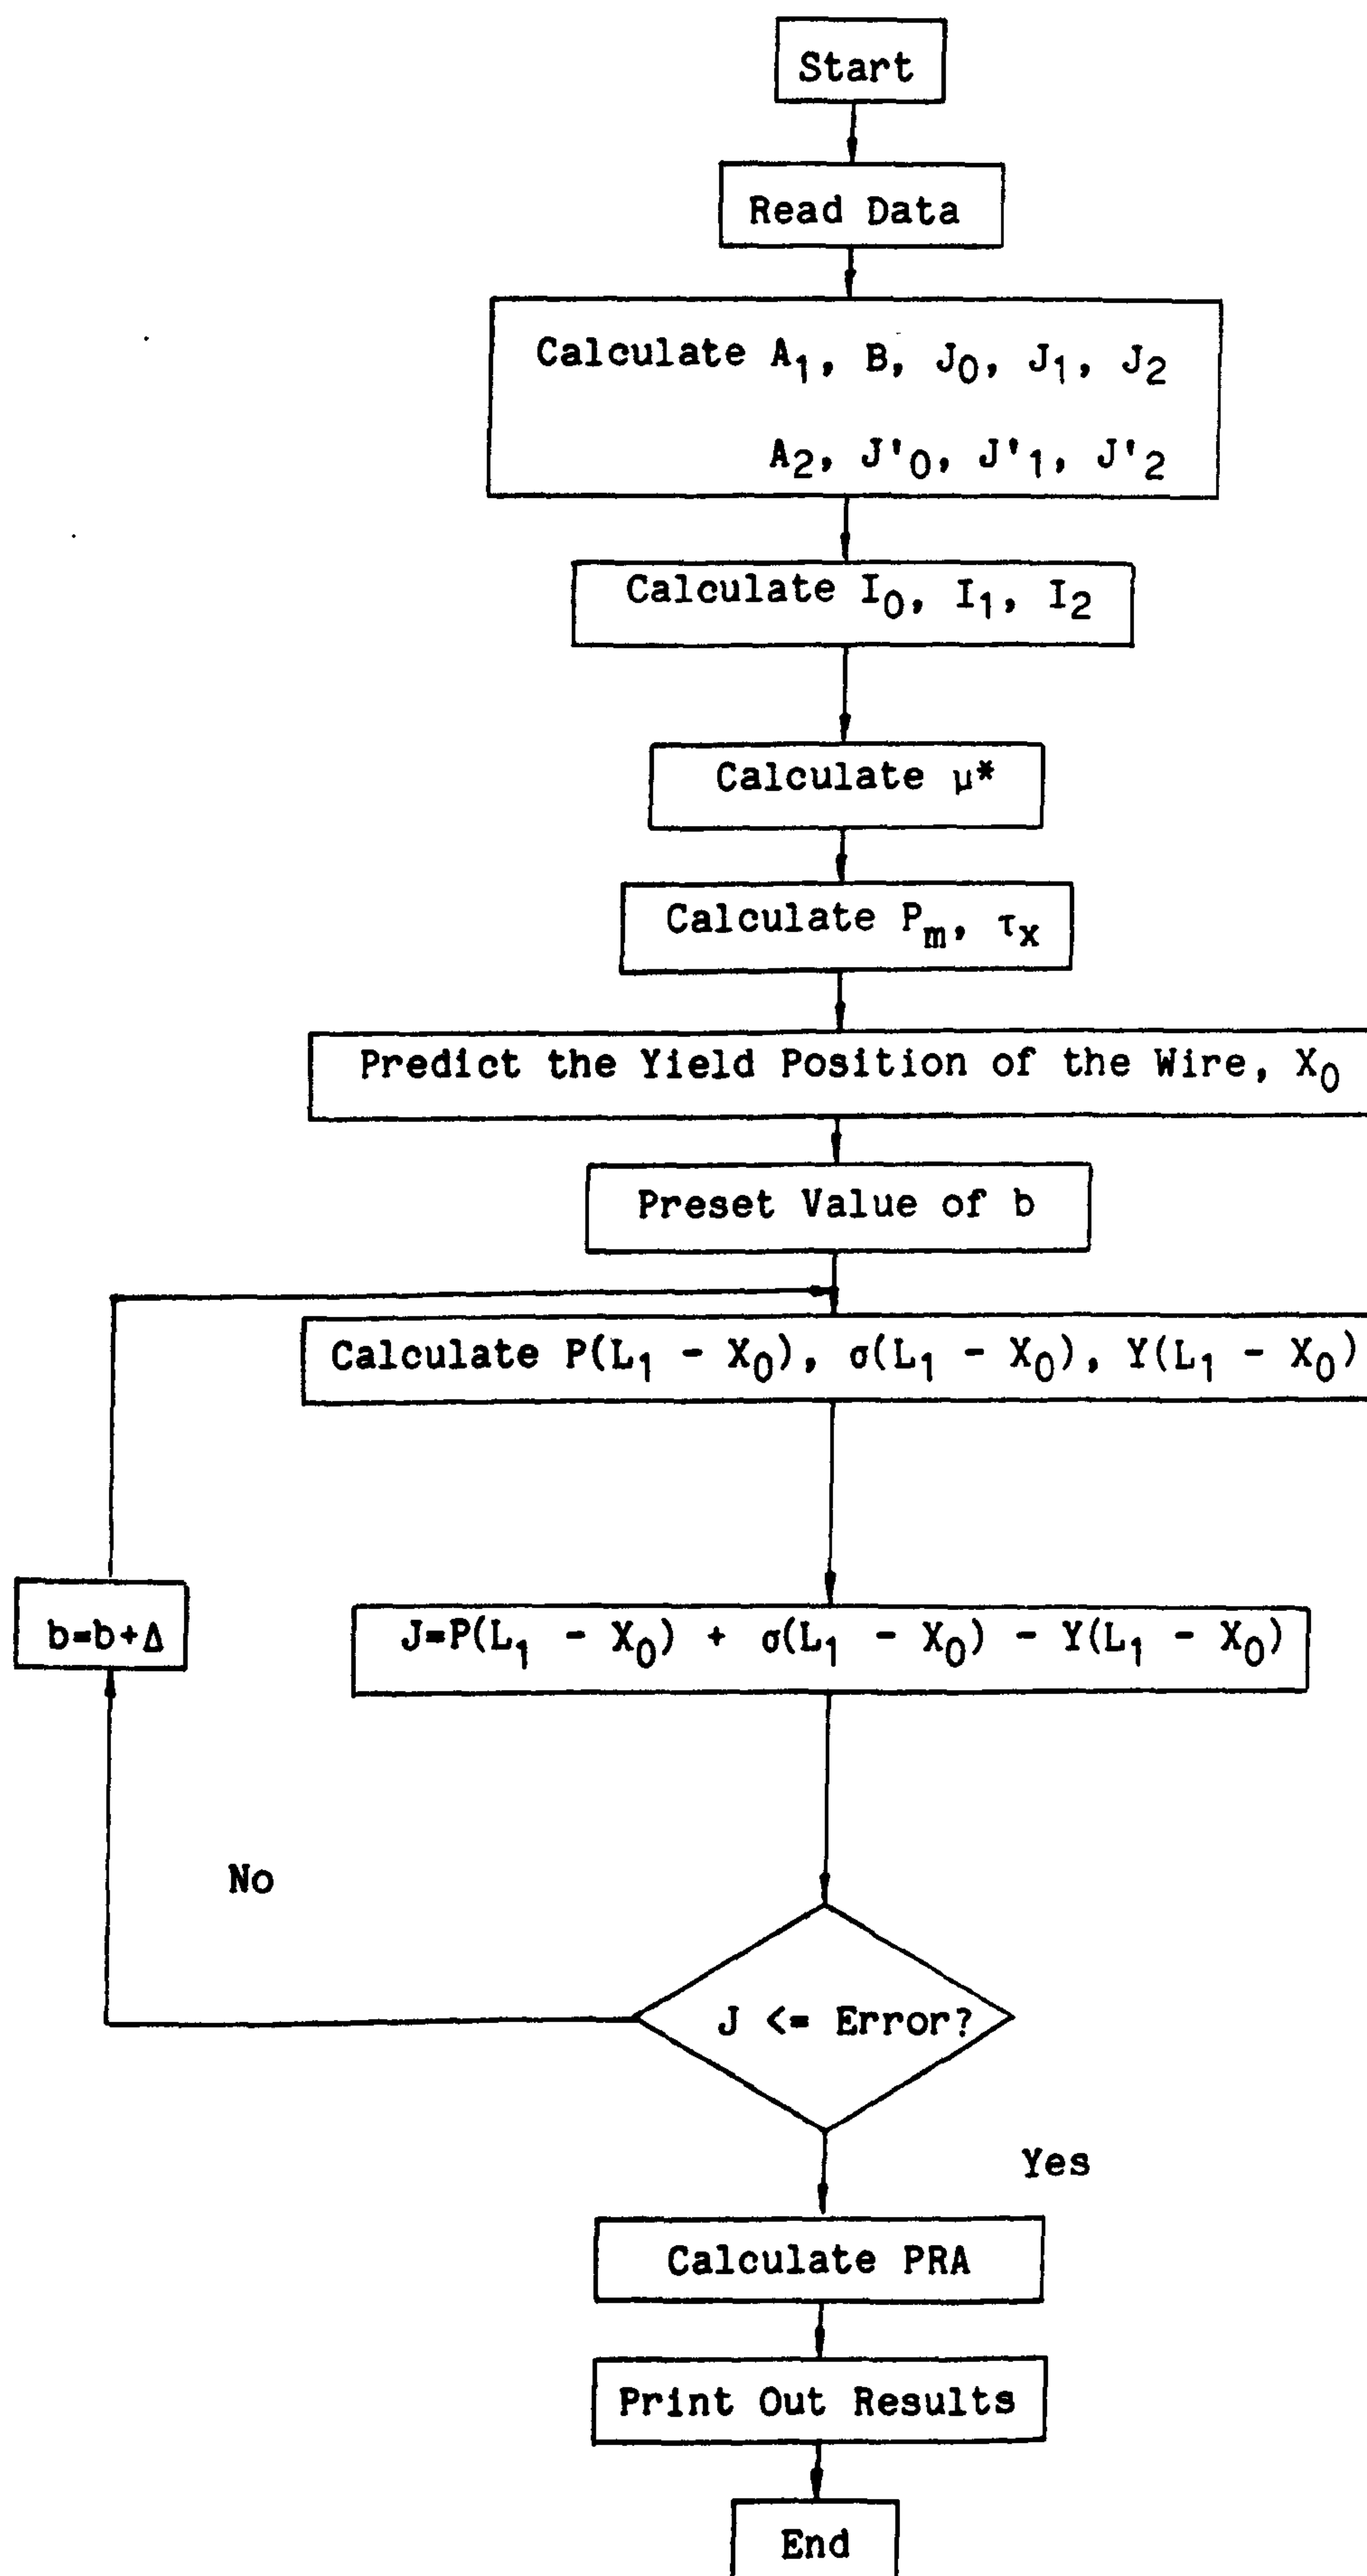

Then equation (A3.6) becomes

$$\frac{\rho c u_0 L_1}{k} \left(\frac{h}{L_1} \right)^2 u' \frac{\partial T}{\partial X'} = \left[\frac{\partial^2 T}{\partial Y'^2} + \left(\frac{h}{L_1} \right)^2 \frac{\partial^2 T}{\partial X'^2} \right] + \frac{\mu u_0^2}{k} \left(\frac{\partial u'}{\partial Y'} \right)^2 \quad (A3.7)$$

With $h / L_1 \ll 1$, the left-hand side of equation and the second term in the brackets on the right-hand side of equation (A3.7) can be neglected. Thus the energy equation applied to the process of dieless wire drawing is given by

$$\frac{\partial^2 T}{\partial Y'^2} = - \frac{\mu}{k} \left(\frac{\partial u}{\partial Y} \right)^2 \quad (A3.8)$$

Appendix 10 : Controller Algorithm Implemented on the MC68000 Microcomputer

16-bit Fixed-Point Arithmetic

The algorithm is implemented in 16-bit fixed-point arithmetic on the MC68000 microcomputer. The representation of a word is shown in Fig. A10.1.

Fig. A10.1 One Fixed-Point Word

In this format, a 16-bit number is composed of 1 bit sign, 7 bit integer and 8 bit fraction, and it lies in the range of $-128 < X < 127.996$. Selection of this range, however, causes overflows in computation. Thus, after every step of computation where overflow may occur, the program will test if the overflow has occurred and, if it has, an overflow treatment subroutine will be called. The input data is a fraction of 8-bit length and the output is also 8-bit length. The input and output of the process should be scaled such that they are the same magnitude. This will improve the numerical conditions in the estimation. The program implemented in MC 68000 assembly language is given as follows. Depending upon the control flowchart in use, the sections of the program are linked.

```
* Motorola 68000 Assembly Language
* n is the number of parameters to be estimated
* For the first order system n=3
*  $Z^T(t) = [ u(t-1), y(t-1), y(t-2) ]$ 
*  $\theta(t) = [ h_0, g_0, g_1 ]$ 
```

```

*
* P(t) =  $\begin{bmatrix} p11 & p12 & p13 \\ p21 & p22 & p23 \\ p31 & p32 & p33 \end{bmatrix}$ 
*
* For the second order system n = 5

* ZT(t) = [ u(t-1), u(t-2), y(t-1), y(t-2), y(t-3) ]
* θ(t) = [ h0, h1, g0, g1, g2 ]
*
* P(t) =  $\begin{bmatrix} p11 & \dots & p15 \\ \vdots & & \vdots \\ p51 & \dots & p55 \end{bmatrix}$ 
*
*
* ZT(t) = [ z1j]
* θ(t) = [ θ1j]
* P(t) = [ pij]
* For first order system i=3, j=3
* For second order system i=5, j=5
*
* MC 6821 I/O interface addressing on MC68000 education computer board
* PRA Peripheral Register A
* PRB Peripheral Register B
* MC68230 PI/T addressing on the MC68000 education microcomputer board

Floating-point arithmetic

It is generally impractical to employ floating-point representation in computers with less than 24 bit per word, since the precision (number of significant digits in the fraction) is not sufficient for most applications [53]. However, simulation experience and practical application showed that a fractional-part of 16-bits would be adequate for on line self-tuning algorithm [41].

To improve the accuracy of computation, software was rewritten in 24-bit floating-point arithmetic on 16-bit MC 68000 microcomputer. The representation of a floating-point word is shown in Fig. A10.2.

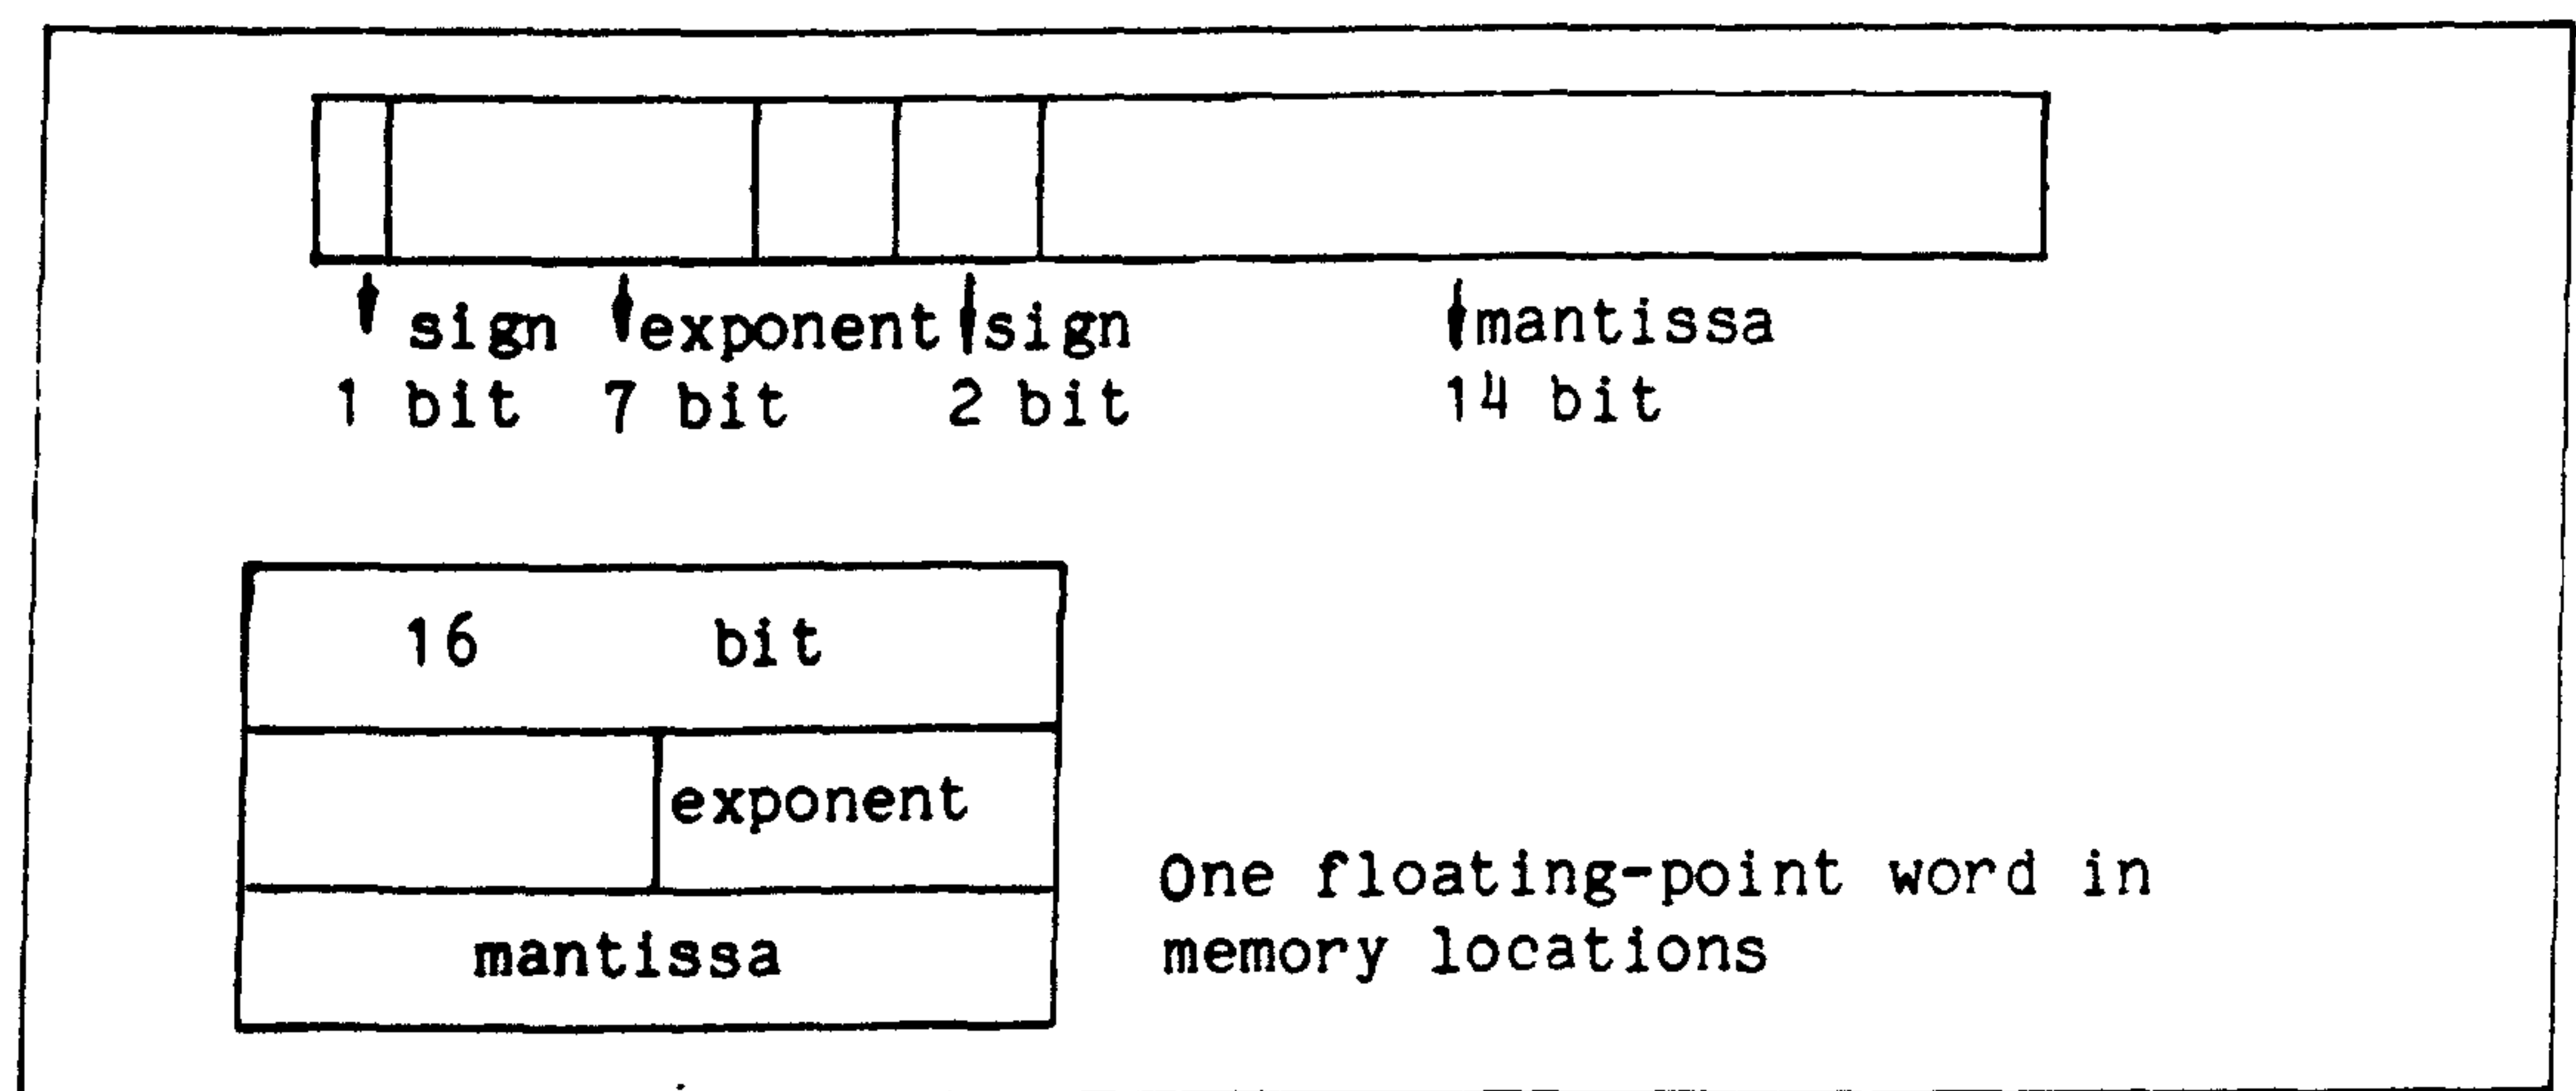

Fig. A10.2 One Floating-Point Word

In this format, the floating-point numbers lie in the range of $1.47 \times 10^{-39} < x < 1.70 \times 10^{+38}$. Numbers represented with 3 bytes make it possible to optimise floating-point calculations using 16-bit MC 68000; the operation time is only about 100 ms and this is not likely to cause any problem for most of processes.

The algorithm implemented in MC 68000 assembly language is given as follows. In this case, both input and output data are integers of 8-bit length.

```

* Motorola 68000
* 24-bit floating-point arithmetic
* Self-tuning PID algorithm

```

Appendix 11 : Experimental Results in Tabular Form

This Appendix contains some experimental results which are classified and tabulated as follows:

Table 1-8 are experimental results obtained using the stepped bore reduction unit.

Table 1 : Copper wire - WVG 23, 110°C

Table 2 : Copper wire - WVG 23, 120°C

Table 3 : Copper wire - Nylon 6, 240°C

Table 4 : Copper wire - Nylon 6, 260°C

Table 5 : Copper wire - Nylon 6, 280°C

Table 6 : Copper wire - ELVAX 650, 140°C

Table 7 : Copper wire - ELVAX 650, 150°C

Table 8 : Copper wire - ELVAX 650, 160°C

Table 9 : Temperature step response of the polymer melt chamber

Table 10 : Closed-loop step response of the polymer melt chamber

Table 11 : Speed step response of the hydraulic drive system

Table 12 : Sampled data / output data of the microcomputer

Table 13 : Open-loop step response of the speed control system

Table 14 : Fluctuation of the PRA readings after a rapid change in drawing speed

Table 15 : PRA / length of the produced wire, ELVAX 650, 150°C

Table 16 : PRA / length of the produced wire, ELVAX 650, 150°C

THE OPTIMISATION OF A PLASTO-HYDRODYNAMIC WIRE-DRAWING PROCESS

G. R. Symmons[†], M. S. J. Hashmi^{*} and Y. D. Xie[†]

[†] Sheffield City Polytechnic, England
^{*} N.I.H.E. Dublin, Ireland.

ABSTRACT

Non linear equations have been formulated for the pressure and axial stress increment in a conical orifice filled with a viscous fluid through which a circular cross section solid continuum is being pulled. The viscous fluid was assumed to be non Newtonian, where the viscosity is dependent upon pressure and the continuum was assumed to be rigid nonlinearly strain hardening.

A finite-differences numerical technique has been applied to solve these equations to enable predictions to be made of the non linear deformation profile of the continuum. Computer results on the effects of changes in geometry of the conical orifice on the magnitude and extent of deformation of the wire are presented in graphical form.

KEYWORDS

Plasto-hydrodynamics, wire-drawing, die-less, non Newtonian fluids, non linear strain hardening.

INTRODUCTION

In conventional drawing of wire, the diameter is reduced by pulling it through a reduction die, resulting in wear and time dependent size of product. A developed technique (1,2) enables the wire diameter to be reduced without using any conventional reduction die. In this process the wire is pulled through a tubular orifice of tapered bore which is filled with a viscous fluid. An important feature of the process is that the smallest bore size of the orifice is always greater than the diameter of the undeformed wire and hence no metal to metal contact takes place.

The pulling action of the wire through the viscous fluid gives rise to a drag force and generates hydrodynamic pressure on the wire. The magnitude of the combined drag force and pressure generated depend upon the type of fluid and geometric configuration of the orifice. By design and optimisation the combined drag force and pressure initiates plastic yielding and permanent deformation to the wire.

In order to optimise the process to give its full potential it is necessary to analyse the mechanics of the deformation process inside the tubular process. In references (3,4) closed form analytical solutions were presented based upon predetermined deformation profiles. An improved method of determining deformation values using a finite-difference technique was presented in (5), assuming a Newtonian fluid with a rigid nonlinearly strain hardening wire.

High pressures are generated in an optimised condition to cause deformation of the wire such that the effect of pressure on the viscosity of the fluid becomes significant. The present analysis uses a finite-difference technique assuming a non Newtonian fluid dependent upon pressure with a rigid non-linearly strain

hardening wire. The results enable the geometry of the orifice to be optimised for maximum reduction in area of the wire.

ANALYSIS

The analysis is based on the geometrical configuration shown in Fig. 1a. where a round continuum, diameter D_1 is pulled through a tapered orifice filled with a fluid, the gap at any point is given by

$$h = h_1 - kx$$

where

$$k = (h_1 - h_2)/B$$

In order to establish a mathematical formulation of the process the following assumptions are made:

- (i) the fluid has a viscosity which is independent upon shear stress but dependent upon pressure
 $\mu = \mu_0 e^{\alpha p}$ and $\tau = \frac{\partial u}{\partial y}$
- (ii) flow is axial and laminar
- (iii) the thickness of the fluid layer is small compared to the bore of the orifice, and
- (iv) the pressure in the fluid is uniform in the thickness direction at any point along the length of the orifice, $\mu = \mu(x)$.

Considering the hydrodynamics of the fluid

$$\frac{dp}{dx} = \frac{\partial \tau}{\partial y} \text{ for equilibrium}$$

hence the velocity distribution in the gap is given by

$$u = \frac{1}{2\mu} \left(\frac{dp}{dx} \right) (y^2 - hy) + V(1-y/h)$$

for the boundary conditions $u = 0$ at $y = h$ and $u = V$ and $y = 0$.

The flow of the fluid in the direction of pull is

$$Q_x = \int_0^h u dy = - \frac{h^3}{12\mu} \left(\frac{dp}{dx} \right) + \frac{Vh}{2}$$

For steady state conditions

$$\frac{h^3}{6\mu} \left(\frac{dp}{dx} \right) = Vh + \text{Constant}$$

boundary condition when $x = \bar{x}$, $p = \text{max}$,

hence constant = $-\bar{V}h$

where $\bar{h} = h_1 - Kx$

$$\therefore \frac{dp}{dx} = 6\mu V \left(\frac{1}{h^2} - \frac{\bar{h}}{h^3} \right)$$

substituting for $\mu = \mu_0 e^{ap}$

$$\frac{dp}{dx} = 6\mu_0 e^{ap} V \frac{1}{(h_1 - Kx)^2} - \frac{\bar{h}}{(h_1 - Kx)^3} \quad (1)$$

integrating and applying the boundary condition $p = 0$ at $x = 0$

$$p = -\frac{1}{a} \ln \left[1 - \frac{6\mu_0 Va}{K} \left(\frac{1}{h_1 - Kx} - \frac{\bar{h}}{2(h_1 - Kx)^2} \right) - \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) \right] \quad (2)$$

Position of maximum pressure

Applying the boundary condition $p = 0$ at $x = B$ where $h_1 - Kx = h_2$, the right hand side of equation must be unity i.e.

$$1 - \frac{6\mu_0 Va}{K} \left(\frac{1}{h_2} - \frac{\bar{h}}{2h_2^2} \right) - \frac{1}{h_1} + \frac{\bar{h}}{2h_1^2} = 1$$

$$\therefore \bar{h} = \frac{2h_1 h_2}{h_1 + h_2} \quad (3)$$

and

$$\bar{x} = \frac{h_1 B}{h_1 + h_2} \quad (4)$$

Axial stress in the wire prior to deformation

An axial stress in the wire will be produced by the shear stresses in the fluid acting on the surface of the wire.

Substituting the velocity gradient of the fluid into

$$\tau = \mu \frac{\partial u}{\partial y} \text{ gives } \tau = \frac{1}{2} \left(\frac{dp}{dx} \right) (2y - h) - \frac{\mu V}{h}$$

$$\text{at } y = 0 \quad \tau_x = -\frac{h}{2} \left(\frac{dp}{dx} \right) - \frac{\mu V}{h} \quad (5)$$

Substituting for $\frac{dp}{dx}$ from equation (1) into (5)

$$\tau_x = \mu_0 V e^{ap} \left(\frac{3\bar{h}}{(h_1 - Kx)^2} - \frac{4}{h_1 - Kx} \right) \quad (6)$$

From equation (2)

$$e^{ap} = \frac{1}{1 - \frac{6\mu_0 Va}{K} \left(\frac{1}{h_1 - Kx} - \frac{\bar{h}}{2(h_1 - Kx)^2} \right) - \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right)} \quad (7)$$

The drag force $F = \int_0^x \pi D_1 \tau_x dx$

$$\text{Axial stress } \delta_x = \frac{4F}{\pi D_1^2} = \frac{4}{D_1^2} \int_0^x \tau_x dx \quad (8)$$

Substituting τ_x and e^{ap} from equations (6) and (7) respectively and integrating gives the solution δ_x for two conditions

$$(1) \text{ when } 12\mu_0 \bar{h} Va \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) + 2\bar{h}K - 6\mu_0 Va > 0$$

$$\delta_x = A_1 + A_2 \left(\tan^{-1} \frac{2KA_1 x + \frac{6\mu_0 Va (\bar{h} - h_1)}{h_1} - 2h_1 K}{\sqrt{6\mu_0 Va A_1}} - \tan^{-1} \frac{6\mu_0 Va (\bar{h} - h_1)}{h_1} - 2h_1 K \right) \quad (9)$$

$$\text{where } A_1 = \left| 12\mu_0 \bar{h} Va \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) + 2\bar{h}K - 6\mu_0 Va \right|$$

$$A_2 = 6\mu_0 Va \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) + K$$

$$A_3 = \frac{8V\mu_0}{D_1 A_1} \ln \left| \left(1 - \frac{Kx}{h_1} \right) - \frac{6\mu_0 Va}{Kh_1^2} \left(h_1 - Kx - \frac{\bar{h}}{2} - \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) (h_1 - Kx)^2 \right) \right|$$

$$A_4 = \left(3\bar{h} - \frac{2}{\frac{1}{h} - \frac{\bar{h}}{2h_1^2} + \frac{K}{6\mu_0 Va}} \right) \frac{2}{\sqrt{6\mu_0 Va A_1}}$$

and

$$(11) \text{ when } 12\mu_0 \bar{h} Va \left(\frac{1}{h_1} - \frac{\bar{h}}{2h_1^2} \right) + 2\bar{h}K - 6\mu_0 Va < 0$$

$$\delta x = A_1 + A_4 - \ln \left| \frac{(2KA_1 x + B_2 - B_1 B_2 + B_1)}{(2KA_1 x + B_2 + B_1 B_2 - B_1)} \right| \quad (10)$$

$$\text{where } B_1 = 2h_1 K + \sqrt{6\mu_0 Va A_1}$$

$$B_2 = \frac{6\mu_0 Va (\bar{h} - h_1)}{h_1}$$

$$B_3 = -2h_1 K + \sqrt{6\mu_0 Va A_1}$$

Plastic yielding

The combined effects of the axial stress and the hydrodynamic pressure can cause plastic yielding of the continuum if the yield criteria is satisfied. If the material of the continuum is assumed to be rigid non linearly strain hardening then the flow stress can be expressed as

$$Y = Y_0 + A\epsilon^n \quad (11)$$

then according to the Tresca yield criterion, plastic yielding will commence at a point x_0 provided that

$$p + \delta x = Y_0$$

Once plastic yielding has commenced, strain hardening of the material will take place and yielding will continue as long as

$$p + \delta_x = Y > Y_0 + A\epsilon^n \quad (12)$$

The deformation zone

Consider the geometrical configuration shown in Fig 1b and an element of continuum being deformed in Fig 1c. A finite difference technique is adopted to express the pressure and axial stress equations between two points Δx distance apart on the deforming continuum assuming the deformation takes place linearly. It is assumed that deformation ceases at $x = \bar{x}$ where

$$\frac{dp}{dx} = 0$$

Equation (1) when expressed in finite difference form gives the pressure values at different points, distance Δx apart.

$$P_1 = P_{1-1} + 6\mu_1 V_1 \Delta x \left(\frac{1}{h_1^2} - \frac{\bar{h}}{h_1^3} \right) \quad (13)$$

where

$$V_1 = V_{1-1} (D_{1-1}/D_1)^2$$

$$D_1 = D_{1-1} - 2b_1 \Delta x$$

$$h_1 = h_{1-1} - (K-b_1) \Delta x$$

$$\mu_1 = \mu_0 e^{aP_{1-1}}$$

The equilibrium condition for a small element being deformed shown in Fig 1c gives

$$d\sigma_x = -2 \frac{dD}{D} (\gamma + \tau_x \cot \alpha)$$

$$\text{where } D = D_1 - 2bx \therefore dD = -2bdx$$

$$\text{and } \cot \alpha = -1/2b$$

hence the axial stress in the continuum can be expressed in finite difference form

$$\delta_{x1} = \delta_{x1-1} \frac{4b_1 \Delta x Y_1}{D_1} - \frac{4\Delta x \mu_1}{D_1 h_1} \left(4V_1 - \frac{3V_1 \bar{h}}{h_1} \right) \quad (14)$$

where

$$Y_1 = Y_0 + A \{ \ln(D_1/D_0) \}^n \quad (15)$$

Deformation of the continuum continues as the plasto-hydrodynamic compatibility equation is satisfied

$$P_1 + \delta_{x1} = Y_1$$

The procedure for predicting the theoretical results involved the determination of x_0 , the distance from the entry of the orifice where plastic deformation commences. This position satisfies the equation $p + \delta_x = Y_0$ and is found by iterative computation of equations (2), (8) and Y_0 . From this point onward, the extent of the plastic deformation is known. Equations (13) and (14) are combined for small increments Δx to equate to equation (15) and the slopes b are found by iterative computation. The deformation profile and percentage reduction in area are predicted for changes in drawing speed and orifice geometry.

Notations

- B = Length of the orifice
- D = Diameter of wire
- F = Drag force
- V = Pulling velocity
- P = Hydrodynamic pressure
- τ_x = Shear stress at fluid/wire interface
- δ = Axial stress in wire
- Y = Yield stress of wire material
- h = Gap between wire and orifice
- μ = Dynamic viscosity of fluid
- x = Distance along orifice from leading edge
- y = Distance from wire surface into gap
- a = Viscosity pressure coefficient
- b = Deformation profile constant
- c = Plastic strain in the wire
- n = Strain hardening coefficient
- A = Material constant

RESULTS AND DISCUSSION

Theoretical results were calculated on standard values of parameter obtained from experimental studies. The equations governing the deformation zone were solved at steps of

$$\Delta x = \frac{x_0 - \bar{x}}{15}$$

from the position of the onset of yield x_0 .

The data below were the parameters used:
length of orifice B = 45mm, inlet gap $h_1 = 0.5$ mm, outlet gap $h_2 = 0.075$ mm, initial diameter of wire $D_1 = 1.625$ mm, viscosity of fluid at normal pressure $\mu_0 = 120$ Ns/m², viscosity constant relating to pressure $a = 2.0 \times 10^{-8}$, initial yield stress of continuum $Y_0 = 100$ MN/m², material constant $A = 341$ MN/m² and strain hardening index $n = 0.25$.

Fig 2 shows the hydrodynamic pressure profile generated in the orifice when pulling the wire at 0.31m/s. The effect of non-Newtonian behaviour can be observed with the steep increase in pressure approaching the maximum at 38mm along the orifice. A maximum pressure of 160 MN/m² can be generated in the fluid by hydrodynamic means, with a shape factor $K = 0.0094$.

The onset of yield in the wire begins when the sum of the hydrodynamic pressure and the axial stress equals the yield stress of the wire material. Fig 3 shows the computer results of the position of the onset of yield in the orifice. This position is dependent upon drawing speed and shape factor K and the graph shows the optimum value of K for three speeds. For the standard values of parameters stated above, a low K value in the region of 0.001 provides early deformation in the orifice.

The completion of yielding is at the maximum pressure position because there is a change of sign of the pressure gradient. The Poiseuille type flow is then in opposition to the Couette flow thus significantly reducing the shear stress together with the reduction in pressure. Fig 4 shows this position for changes in the outlet and inlet fluid gaps. A high value of K extends the maximum pressure position towards the outlet end of the orifice. There is therefore a conflict in the optimised requirements for x_0 and \bar{x} in terms of K . Optimisation of K to produce a long length of deformation profile is therefore a more practical way of gaining maximum reduction in area. Fig 5 shows the computer results for the length of deformation for three drawing speeds and a K value in the region of 0.002 give maximum lengths.

Deformation profiles for three drawing speeds are given in Fig 6 and a comparison of theoretical profile with an experimental profile from ref (5) is given in Fig 7. Comparison of the experimental and theoretical deformation profiles are for the same level of percentage reduction in area of 23%. Although there is a mismatch in the drawing speeds to attain a common percentage reduction in area, the difference is significantly less than the Newtonian Solution in (5).

Finally, Fig 8 shows the changes of maximum drag force F_{max} , length of deformation zone L and percentage reduction in area PRA against K . The effect of change in K is significant and optimises to a maximum of 0.0023.

CONCLUSIONS

A numerical solution has been developed to predict the deformation of wire drawn through a conical orifice filled with a non-Newtonian fluid.

For the same extent of deformation the theoretically predicted profiles show a closer agreement to observed experimental results than a previous Newtonian solution.

At drawing speeds in excess of 1m/s, the agreement between actual and predicted percentage reduction in area is poor. However at low drawing speeds, the optimisation technique described in this paper is valid for the design of the orifice in this new process.
